2

3 **7.SM.1.1 Simplified expressions for greenhouse gases**

4

5 In Section 7.3.2 and Table 7.5, simplified expressions for the stratospheric-temperature-adjusted radiative  
6 forcing (SARF) are used to convert greenhouse gas (GHG) concentrations to radiative forcing. AR5 (Myhre  
7 et al., 2013b) used relationships first introduced in Myhre et al. (1998), providing a logarithmic dependence  
8 of carbon dioxide (CO<sub>2</sub>) SARF on CO<sub>2</sub> concentrations, and square root dependencies of methane (CH<sub>4</sub>) and  
9 nitrous dioxide (N<sub>2</sub>O) SARF on CH<sub>4</sub> and N<sub>2</sub>O concentrations. The CH<sub>4</sub> and N<sub>2</sub>O relationships accounted for  
10 band overlaps between these gases. These simplified expressions for SARF were revised in Etminan et al.  
11 (2016) using updated spectroscopic data. The most notable changes were a substantial revision in the  
12 methane RF of about +25% to account for previously neglected shortwave effects (Section 7.3.2.2) and  
13 inclusion of the mutual band overlap between carbon dioxide and nitrous oxide (Section 7.3.2.1). In Etminan  
14 et al. (2016), calculations from the Oslo line-by-line (LBL) radiative transfer model were conducted for 48  
15 cases that co-varied concentrations of carbon dioxide, methane and nitrous oxide that spanned values from  
16 180–2000 ppm CO<sub>2</sub>, 340–3500 ppb CH<sub>4</sub> and 200–525 ppb N<sub>2</sub>O. These ranges were selected to cover the  
17 minimum observed from ice core records during the Last Glacial Maximum to the maximum projected in the  
18 RCP8.5 scenario in the future (Meinshausen et al., 2011b; Riahi et al., 2011). Simplified relationships  
19 linking concentrations of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O to the SARF from each gas, including overlaps, were provided  
20 from these 48 different cases that fit the original line-by-line results within a few percent.

21

22 A more accurate but complex functional fit was provided in Meinshausen et al. (2020) to the 48 Oslo LBL  
23 cases in Etminan et al. (2016). Two main advantages to the Meinshausen et al. (2020) fit are (i) the reduced  
24 error in the new fits to the original Oslo LBL results (maximum 0.11% for the CO<sub>2</sub> cases compared to 3.6%  
25 in Etminan et al. (2016)) and (ii) the extension of the valid range of the fits to CO<sub>2</sub> concentrations above  
26 2000 ppm, which occurs in SSP5-8.5 in the future (though not RCP8.5). One drawback to the Meinshausen  
27 et al. (2020) fit compared to the original Etminan et al. (2016) fit is that the former is defined with respect to  
28 1750 greenhouse gas concentrations, and requires a re-calculation of the coefficients to use baseline  
29 concentrations that are different from this, whereas the Etminan et al. (2016) fit is valid for any baseline  
30 concentration within their stated validity range (180–2000 ppm CO<sub>2</sub>, 340–3500 ppb CH<sub>4</sub>, 200–525 ppb  
31 N<sub>2</sub>O). In general, AR6 and Chapter 7 in particular reports SARF and effective radiative forcing (ERF)  
32 relative to a 1750 baseline, negating this possible drawback, and so the Meinshausen et al. (2020)  
33 relationships are used for computing SARF and ERF throughout Chapter 7 and in Annex III. The  
34 relationships converting concentrations to SARF are shown in Table 7.SM.1. For halogenated greenhouse  
35 gases with concentrations in the ppt range, SARF remains a linear function of concentrations, as in AR5.

36

37

39

40 **Table 7.SM.1:** Simplified expressions to compute radiative forcing (RF) from concentrations of greenhouse gases  
41 (Myhre et al., 1998; Meinshausen et al., 2020).  $C$ ,  $N$  and  $M$  refer to concentrations of CO<sub>2</sub> in ppm,  
42 N<sub>2</sub>O in ppb and CH<sub>4</sub> in ppb, respectively.

43

Gas	Radiative forcing (SARF) simplified expression	Coefficients
CO <sub>2</sub>	$C_{\alpha_{\max}} = C_0 - \frac{b_1}{2a_1}$ $\alpha' = \begin{cases} d_1 - \frac{b_1^2}{4a_1}, & C > C_{\alpha_{\max}} \\ d_1 + a_1(C - C_0)^2 + b_1(C - C_0), & C_0 < C < C_{\alpha_{\max}} \\ d_1, & C < C_0 \end{cases}$ $\alpha_{N_2O} = c_1\sqrt{N}$ $\text{SARF}_{CO_2} = (\alpha' + \alpha_{N_2O}) \cdot \ln\left(\frac{C}{C_0}\right)$	$a_1 = -2.4785 \times 10^{-7} \text{ W m}^{-2} \text{ ppm}^{-2}$ $b_1 = 7.5906 \times 10^{-4} \text{ W m}^{-2} \text{ ppm}^{-1}$ $c_1 = -2.1492 \times 10^{-3} \text{ W m}^{-2} \text{ ppb}^{-1/2}$ $d_1 = 5.2488 \text{ W m}^{-2}$ $C_0 = 277.15 \text{ ppm}$
N <sub>2</sub> O	$\text{SARF}_{N_2O} = (a_2\sqrt{C} + b_2\sqrt{N} + c_2\sqrt{M} + d_2) \cdot (\sqrt{N} - \sqrt{N_0})$	$a_2 = -3.4197 \times 10^{-4} \text{ W m}^{-2} \text{ ppm}^{-1}$ $b_2 = 2.5455 \times 10^{-4} \text{ W m}^{-2} \text{ ppb}^{-1}$

		$c_2 = -2.4357 \times 10^{-4} \text{ W m}^{-2} \text{ ppb}^{-1}$ $d_2 = 0.12173 \text{ W m}^{-2} \text{ ppb}^{-1/2}$ $N_0 = 273.87 \text{ ppb}$
CH <sub>4</sub>	$\text{SARF}_{\text{CH}_4} = (a_3\sqrt{M} + b_3\sqrt{N} + d_3) \cdot (\sqrt{M} - \sqrt{M_0})$	$a_3 = -8.9603 \times 10^{-5} \text{ W m}^{-2} \text{ ppb}^{-1}$ $b_3 = -1.2462 \times 10^{-4} \text{ W m}^{-2} \text{ ppb}^{-1}$ $d_3 = 0.045194 \text{ W m}^{-2} \text{ ppb}^{-1/2}$ $M_0 = 731.41 \text{ ppb}$
Halogenated compounds and other minor GHGs	$\text{SARF}_X = e_X(X - X_0)$	$X$ and $X_0$ in ppb $e_X$ is radiative efficiency ( $\text{W m}^{-2} \text{ ppb}^{-1}$ ) (Table 7.SM.7)

4

5

### 7.SM.1.2 Effective radiative forcing from a doubling of CO<sub>2</sub>

6

7 In Section 7.3.2.1, the ERF from a doubling of CO<sub>2</sub> ( $\Delta F_{2 \times \text{CO}_2} = 3.93 \text{ W m}^{-2}$ ) is defined relative to 1750 CE  
8 concentrations of CO<sub>2</sub> assessed in Chapter 2 ( $C_0 = 278.3 \text{ ppm}$ ) and N<sub>2</sub>O ( $N_0 = 270.1 \text{ ppb}$ ) using the  
9 Meinshausen et al. (2020) fits (Table 7.SM.1) to calculate SARF of  $3.75 \text{ W m}^{-2}$  and then adding an  
10 additional 5% for tropospheric adjustments (Section 7.3.2.1; Table 7.3). Using the Etminan et al. (2016) fits  
11 with the same baseline concentrations ( $C_0 = 278.3 \text{ ppm}$ ,  $N_0 = 270.1 \text{ ppb}$ ) results in a SARF of  $3.80 \text{ W m}^{-2}$   
12 and an ERF of  $3.99 \text{ W m}^{-2}$  (Table 7.SM.2). The simplified expressions are used as no specific line-by-line  
13 experiment was performed for a doubling of CO<sub>2</sub> from about 1750 concentrations in Etminan et al. (2016).  
14

14

15 Alongside the choice of simplified expression, the baseline CO<sub>2</sub> and N<sub>2</sub>O concentrations also has an impact  
16 on the SARF and ERF from a doubling of CO<sub>2</sub> (Table 7.SM.2). Using 1850 CE baselines results in ERF  
17 values that are close, but not exactly the same, as using 1750 CE baselines (Table 7.SM.2). Using a present-  
18 day baseline results in estimates of SARF and ERF from a doubling of CO<sub>2</sub> that are about 1% greater than  
19 the 1750 or 1850 values (Table 7.SM.2). The 1850 baseline is significant as it the reference pre-industrial  
20 state for CMIP6 experiments, including the *abrupt4xCO2* and *1pctCO2* experiments used to estimate ECS  
21 and TCR from climate models. It should be noted that the *1pctCO2* experiment design relies on a logarithmic  
22 increase in CO<sub>2</sub> SARF with concentration to estimate TCR (Gregory et al., 2015), and both the Etminan et al.  
23 (2016) and Meinshausen et al. (2020) SARF formulas are super-logarithmic with increasing CO<sub>2</sub>  
24 concentrations.  
25

### 7.SM.1.3 Historical (1750-2019) effective radiative forcing time series

#### 7.SM.1.3.1 Best estimate historical time series

The historical ERF time series describes how the best estimates of changes in climate drivers translates to ERF for 1750 to 2019. The time-evolution of ERF is reported separately for CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, other well-mixed greenhouse gases (WMGHGs), ozone, stratospheric water vapour from methane oxidation, contrails and aviation-induced cirrus, aerosol-radiation interactions, aerosol-cloud interactions, light-absorbing particles on snow and ice, land-use change, volcanic, and solar. The contributions from 49 halogenated GHGs comprising the “other well-mixed greenhouse gases” category are further reported individually. Data is published in Annex III.

For CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O, the SARFs are calculated using time-dependent best-estimate concentrations of these gases from Chapter 2 using the formulae in Table 7.SM.1 and using concentrations from Chapter 2 in 1750 CE as baselines ( $C_0 = 278.3$  ppm,  $N_0 = 270.1$  ppb,  $M_0 = 729.2$  ppb). Tropospheric adjustments of +5% for CO<sub>2</sub>, -14% for CH<sub>4</sub> and +7 % are then added to these SARF values to produce ERF (Section 7.3.2). For 49 halogenated greenhouse gases, concentration changes since 1750 are used combined with radiative efficiencies detailed in Table 7.SM.7 to derive SARF (Table 7.SM.1). Accounting for tropospheric adjustments adds +13% and +12% to CFC-11 and CFC-12 respectively when moving from SARF to ERF. No tropospheric adjustments are assumed for other halogenated species (Section 7.3.2.4).

For historical ozone forcing, the time series from 1750 to 2020 from Skeie et al. (2020) is adopted, using the multi-model mean ERF from six independent Earth System and chemistry-climate models (BCC-ESM1, CESM2-WACCM6, GFDL-ESM4, GISS-E2-1-H, MRI-ESM2-0 and Oslo-CTM3) that used CMIP6 precursor emissions and interactively calculated ozone burdens using full stratospheric and tropospheric chemistry schemes. From the original 12 models reporting results in Skeie et al. (2020), CNRM-CM6, CNRM-ESM2-1 and E3SM1-0 were excluded as they do not include full stratospheric and tropospheric chemistry, only the first out of the similar models CESM2-WACCM6 and CESM2-CAM6 were used, the input4MIPs forcing estimate (Checa-Garcia et al., 2018) was excluded as it did not use CMIP6 precursor emissions, and UKESM-1-0-LL was excluded for having implausible time evolutions of stratospheric ozone that resulted in negative total ozone ERF estimates for 2010 relative to 1850. The extrapolations for the 1750–1850 and 2010–2020 periods (run beyond 2014 using SSP2-4.5) came from a single model (Oslo-CTM3) and results were used up to and including 2019. Stratospheric water vapour from methane oxidation is treated a linear scaling of the methane ERF and scaled to the 1750–2019 assessment of  $0.05 \text{ W m}^{-2}$  (Section 7.3.2.6).

Several forcing categories (contrails, aviation-induced cirrus aerosols, and black carbon on snow) are derived from global annual emissions totals of short-lived climate forcers. For the best estimate of historical emissions from 1750 to 2019, the 11 September 2020 version of the Community Emissions Data System (CEDS) is used (Hoesly et al., 2018), obtained from <https://doi.org/10.5281/zenodo.4025316>. CEDS provides emissions of black carbon (BC), organic carbon (OC), sulphur dioxide (SO<sub>2</sub>), ammonia (NH<sub>3</sub>), nitrogen oxides (NO<sub>x</sub>), carbon monoxide (CO) and non-methane volatile organic compounds (NMVOC) from the fossil fuel, industrial and agricultural sectors. Biomass burning emissions are used from the BB4CMIP dataset (also used for CMIP6 model integrations, from Van Marle et al. (2017)), aggregated into global annual totals. The SSP2-4.5 scenario projection from BB4CMIP is used for 2015-2019.

ERF from contrails and aviation-induced cirrus uses global aviation NO<sub>x</sub> emissions as a predictor of aviation

1 activity following Smith et al. (2018a), and scaled to the 2018 ERF best estimate of  $0.0574 \text{ W m}^{-2}$  from Lee  
2 et al. (2020).

3  
4 ERF from aerosol-radiation interactions (ERFari) was calculated by converting emissions of BC, OC, SO<sub>2</sub>  
5 (representing sulphate aerosol) and NH<sub>3</sub> (representing nitrate aerosol) to forcing using CMIP5-era ACCMIP  
6 multi-model mean contributions for each species from Myhre et al. (2013a) and scaled to obtain the  
7 assessment of  $-0.3 \text{ W m}^{-2}$  for ERFari which is applied to the 2005–2014 decade. ERFari was calculated  
8 using a simple linear relationship to emissions of BC, OC, SO<sub>2</sub> and NH<sub>3</sub> ( $E_{\text{BC}}$ ,  $E_{\text{OC}}$ ,  $E_{\text{SO}_2}$ ,  $E_{\text{NH}_3}$ ):

$$\text{ERFari} = \beta_{\text{BC}}E_{\text{BC}} + \beta_{\text{OC}}E_{\text{OC}} + \beta_{\text{SO}_2}E_{\text{SO}_2} + \beta_{\text{NH}_3}E_{\text{NH}_3} \quad \text{Equation 7.SM.1.1}$$

10 The  $\beta$  coefficients are selected to represent ERFari contributions of  $+0.3 \text{ W m}^{-2}$  from black carbon,  $-0.4 \text{ W}$   
11  $\text{m}^{-2}$  from sulphate,  $-0.09 \text{ W m}^{-2}$  from organic carbon and  $-0.11 \text{ W m}^{-2}$  from nitrate over the 2005–2014  
12 decade, which translates to radiative efficiencies of  $\beta_{\text{BC}} = 50.8 \text{ mW yr m}^{-2} \text{ MtC}^{-1}$ ,  $\beta_{\text{OC}} = -6.21 \text{ mW yr m}^{-2}$   
13  $\text{MtC}^{-1}$ ,  $\beta_{\text{SO}_2} = -3.62 \text{ mW yr m}^{-2} \text{ MtSO}_2^{-1}$ , and  $\beta_{\text{NH}_3} = -2.08 \text{ mW yr m}^{-2} \text{ MtNH}_3^{-1}$ . Newer CMIP6 model  
14 results were not used as fewer model results are available and the complexity of aerosol schemes and internal  
15 mixing in these models makes attribution of aerosol forcing to precursors more difficult than in CMIP5-era  
16 models.

17  
18 ERF from aerosol-cloud interactions (ERFaci) is modelled as a logarithmic function of emissions of SO<sub>2</sub>, BC  
19 and OC following Smith et al. (2018a):

$$\text{ERFaci} = -\beta \ln(1 + E_{\text{SO}_2}/s_{\text{SO}_2} + (E_{\text{BC+OC}}/s_{\text{BC+OC}})) \quad \text{Equation 7.SM.1.2}$$

21 Eq. (7.SM.1.2) is based on the offline model of Ghan et al. (2013) using a functional form developed by  
22 Stevens (2015) with the inclusion of a carbonaceous aerosol term than can influence ERFaci. Eq. (7.SM.1.2)  
23 was tuned to 11 CMIP6 models that provided historical time-varying (1850-2014) ERFaci estimates and a  
24 parameter set of  $\beta$ ,  $s_{\text{SO}_2}$  and  $s_{\text{BC}}$  was obtained for each CMIP6 model. The parameter tunings from these 11  
25 models were used to generate distributions using kernel density estimates from which 100,000 sample  
26 members were drawn and 100,000 candidate ERFaci time series were produced. The best estimate ERFaci  
27 time series is taken from the median of this 100,000-member ensemble, and then scaled to the assessed  
28 ERFaci of  $-1.0 \text{ W m}^{-2}$  for 1750 to 2005–2014.

29  
30 ERF from light-absorbing particles on snow is linear with BC emissions and scaled to the 1750-2019 ERF  
31 assessment of  $0.08 \text{ W m}^{-2}$ .

32  
33 ERF from land-use change is broken down into an albedo component and an irrigation component. The  
34 albedo component follows the historical ERF time series from Ghimire et al. (2014) from 1700 to 2005, and  
35 is extended forward to 2019 using cumulative land-use related CO<sub>2</sub> emissions from the SSP Historical and  
36 SSP2-4.5 scenarios. This follows the treatment in Smith et al. (2018a) and assumes that land-use related CO<sub>2</sub>  
37 is closely related to deforestation and albedo change. The 1750-2019 assessment of  $-0.15 \text{ W m}^{-2}$  is then  
38 applied to the time series. The ERF from irrigation, assessed to be  $-0.05 \text{ W m}^{-2}$  for 1750–2019 (Sherwood et  
39 al., 2018), scales with the albedo component.

40  
41 All anthropogenic components of the ERF described above are expressed relative to a 1750 baseline.

42  
43 Natural forcings comprise solar changes and volcanic eruptions (forcing from galactic cosmic rays is  
44 assessed to be negligible, Section 7.3.4.5). Volcanic ERF is derived from stratospheric aerosol optical depth  
45 (SAOD) using a conversion of  $-20 \times \Delta\text{SAOD}$  (Section 7.3.4.6), or  $\text{ERF} = -20 \times \text{SAOD} + 0.2582 \text{ W m}^{-2}$   
46 using absolute SAOD where SAOD is nominally taken at 550 nm wavelength. The SAOD conversion to  
47 ERF is expressed as an anomaly in SAOD relative to the 500 BCE to 1749 CE mean, so that the mean  
48 volcanic ERF for 500 BCE to 1749 CE is zero. This is in order that the long-term mean GSAT change from  
49 pre-industrial volcanic forcing alone is zero, avoiding a spurious cooling effect when applying the volcanic

1 time series from 1750 onwards to projections in a climate emulator (e.g. Section 7.SM.2). This convention  
2 means that volcanically quiescent years experience a volcanic ERF of up to  $+0.2 \text{ W m}^{-2}$  (even volcanically  
3 quiescent years have some level of background stratospheric aerosol, so volcanic ERFs approaching the  
4 offset value of  $+0.2582 \text{ W m}^{-2}$  are not seen). CMIP6 uses a similar prescription for volcanic forcing in  
5 ESMs, by applying a constant background climatology of SOAD for *piControl* and *ScenarioMIP* runs that is  
6 based on the historical (1850–2014) mean SAOD (Eyring et al., 2016).

7  
8 The SAOD time series is derived from a composite of three datasets: eVolv v3 (Toohey and Sigl, 2017) for  
9 500 BCE to 1900 CE, CMIP6 for 1850 to 1989, and GloSSAC v2 (Kovilakam et al., 2020) from 1979 to  
10 2018. SAOD from GloSSAC v2 is reported at a wavelength of 525 nm and has been converted to 550 nm  
11 using an Ångström exponent of  $-2.33$  (Kovilakam et al., 2020). The 2018 volcanic ERF is repeated for 2019.  
12 The 1850 to 1900 overlap is performed by linearly ramping down the eVolv v3 dataset and linearly ramping  
13 up the CMIP6 dataset. The CMIP6 and GloSSAC v2 data are ramped over the 1979 to 1989 period. In both  
14 cases the correspondences between overlapping periods is good.

15  
16 Solar ERF is calculated using the change in total solar irradiance (TSI) where TSI is taken from the  $^{14}\text{C}$   
17 SATIRE-M reconstruction from PMIP4 (Jungclauss et al., 2017) and converted to ERF using  $\frac{1}{4} \times 0.71 \times 0.72$   
18  $\times \Delta\text{TSI}$  (Section 7.3.4.4). The baseline for TSI is the mean TSI from 6754 BCE to 1744 CE, which  
19 encompasses complete solar cycles in the proxy reconstructions before 1750.

20  
21 Aerosols and solar ERFs in 2019 both differ from the headline assessments given in Sections 7.3.3 and  
22 7.3.4.4 respectively. For aerosols, the assessment in Section 7.3.3 of  $-1.3 \pm 0.7 \text{ W m}^{-2}$  is valid for 1750 to  
23 about 2014, as less evidence is available for trends in how aerosol forcing has evolved in more recent years.  
24 The emissions-based time series provides a best-estimate aerosol ERF for 1750–2019 of  $-1.06 \text{ W m}^{-2}$ , less  
25 negative than the 1750–2014 assessment, owing to a recent decline in precursor emissions since around 2005  
26 from the CEDS dataset and supported by other studies (Paulot et al., 2018; Kanaya et al., 2020). For solar  
27 ERF, the Chapter 7 assessment of  $+0.01 \pm 0.07 \text{ W m}^{-2}$  is for the 6754 BCE to 1744 CE pre-industrial period  
28 to the 2009–2019 solar cycle. The single year 2019, corresponding to a solar minimum, has a solar ERF  
29 of  $-0.02 \text{ W m}^{-2}$  relative to this pre-industrial baseline.

### 30 31 32 *7.SM.1.3.2 Uncertainties in the historical best estimate time series*

33  
34 The uncertainty in the historical ERF time series was generated with a 100,000-member Monte Carlo  
35 ensemble. The forcing components where uncertainty ranges are assumed to be symmetric and Gaussian in  
36 their assessments in Section 7.3 have a scale factor drawn from a Gaussian distribution with mean of unity  
37 and 5–95% uncertainty range determined as a fraction of the best estimate ERF. The forcing components  
38 with symmetric uncertainty ranges are  $\text{CO}_2$  (fractional 5–95% uncertainty 0.12 of the best estimate),  $\text{CH}_4$   
39 (0.20),  $\text{N}_2\text{O}$  (0.16), halogenated gases (0.19 on the basis that the majority are “long-lived”), ozone (0.50),  
40 stratospheric water vapour (1.00), land use change (0.50) and volcanic (0.25). Contrails (and aviation-  
41 induced cirrus) and light-absorbing particles on snow and ice have asymmetric uncertainty ranges and the  
42 fractional uncertainty was determined by considering ranges below and above the best estimate separately,  
43 by dividing the 5<sup>th</sup> percentile by the best estimate to derive the lower uncertainty range and the 95<sup>th</sup> percentile  
44 by the best estimate to determine the upper range, treating them as two halves of a Gaussian distribution. In  
45 each ensemble member the sampled uncertainty scale factor for each component of the forcing is applied to  
46 the whole time series.

47  
48 For aerosols, the  $\text{ERF}_{\text{ari}}$  and  $\text{ERF}_{\text{aci}}$  are treated independently.  $\text{ERF}_{\text{ari}}$  uncertainty is developed by sampling  
49 the radiative efficiency coefficients  $\beta_{\text{BC}}$ ,  $\beta_{\text{OC}}$ ,  $\beta_{\text{SO}_2}$  and  $\beta_{\text{NH}_3}$  in Eq. (7.SM.1.1) as Gaussian distributions  
50 with 5–95% ranges uncertainties of 0.67, 0.78, 0.50 and 0.44, yielding contributions to  $\text{ERF}_{\text{ari}}$  of  $+0.3 \pm 0.2$   
51  $\text{W m}^{-2}$  for BC,  $-0.4 \pm 0.2 \text{ W m}^{-2}$  for sulphate,  $-0.09 \pm 0.07 \text{ W m}^{-2}$  for OC and  $-0.11 \pm 0.05 \text{ W m}^{-2}$  for nitrate  
52 for the 2005–2014 mean with respect to 1750. Each precursor species is sampled independently and the  
53 historical emissions from the CEDS database are used to generate the time series of  $\text{ERF}_{\text{ari}}$ . For  $\text{ERF}_{\text{aci}}$ , the  
54 100,000 generated time series described in Section 7.SM.1.3 are used with one additional step to scale each  
55  $\text{ERF}_{\text{aci}}$  candidate time series to a 2005–2014 mean  $\text{ERF}_{\text{aci}}$  of  $-1.0 \pm 0.7 \text{ W m}^{-2}$  with respect to 1750. This

1 effectively rescales the  $\beta$  coefficients in each ensemble member in Eq. (7.SM.1.2) .

2  
3 The 5–95% range of anthropogenic ERF of 1.96–3.48 W m<sup>-2</sup> (Table 7.8) for 1750–2019 is determined from  
4 the 5<sup>th</sup> and 95<sup>th</sup> percentiles of the year 2019 anthropogenic ERF in this 100,000 member ensemble.

5  
6 For solar forcing, a 0.50 fractional uncertainty was applied to the amplitude of the solar cycle, and a linear  
7 1750 to 2019 trend of  $\pm 0.07$  W m<sup>-2</sup> (5–95%) range was added to this to represent the uncertainty in the  
8 change in the underlying solar forcing (Section 7.3.4.4).

#### 11 7.SM.1.4 SSP and RCP effective radiative forcing time series

12  
13 A similar method to the process described in Section 7.SM.1.3 is used to derive the ERF time series in RCP  
14 and SSP scenarios to 2500 (Annex III; Figure 4.36; Chapter 6; Chapter 9). From 1750 to 2014 the best  
15 estimate and uncertainty SSP projections ERF time series and the historical ERF time series described are  
16 identical. The SSPs diverge from each other, and from the historical best estimate, in 2015. For SSPs, the set  
17 of eight Tier 1 and Tier 2 scenarios defined by *ScenarioMIP* are assessed (SSP1-1.9, SSP1-2.6, SSP4-3.4,  
18 SSP5-3.4-over, SSP2-4.5, SSP4-6.0, SSP3-7.0 and SSP5-8.5). In addition two variants of SSP3-7.0 used  
19 primarily by *AerChemMIP* are presented: one where short-lived climate forcers are set to emissions factors  
20 consistent with strong air-quality controls that are broadly consistent with SSP1-levels of mitigation, SSP3-  
21 7.0-lowNTCF (Collins et al., 2017), plus a further variant of SSP3-7.0-lowNTCF that also takes into account  
22 methane mitigation alongside other short-lived forcers, SSP3-7.0-lowNTCFCH4 (Allen et al., 2021).

23  
24 For 2015 to 2020, a linear transition between the concentrations of well-mixed greenhouse gases provided by  
25 Chapter 2 and the SSP greenhouse gas concentrations from Meinshausen et al. (2020) is performed. From  
26 2020 onwards concentration projections from Meinshausen et al. (2020) are used. The correspondence  
27 between the Chapter 2 assessed time series and Meinshausen et al. (2017) dataset used for the CMIP6  
28 *historical* experiment is good, with a maximum difference of 0.6% from 1850-2014 for the main three  
29 greenhouse gases and 1.4% for N<sub>2</sub>O in 1750 (the slight 1750 concentration differences affects the 2×CO<sub>2</sub>  
30 forcing in the third decimal place; see Table 7.SM.2).

31  
32 For purely emissions-based forcing estimates (aerosols, contrails and aviation-induced cirrus, and black  
33 carbon on snow), a similar 5-year transition between 2015 and 2020 is performed for fossil fuel, industrial  
34 and agricultural emissions. The best-estimate historical emissions to 2019 are provided in the 11 September  
35 2020 version of the CEDS database (<https://doi.org/10.5281/zenodo.4025316>) and the SSP scenario  
36 projections used v5.1 of the RCMIP dataset (obtained from <https://doi.org/10.5281/zenodo.4589756>;  
37 Nicholls et al., (2020)) that provides consolidated regional and sectoral annual emissions totals from the  
38 CMIP6 SSP emissions datasets (Velders et al., 2015; Gidden et al., 2019; Meinshausen et al., 2020).  
39 Biomass burning emissions are used from the SSP emissions projections from Van Marle et al. (2017). The  
40 same parameter sets from the historical ERF estimate and 100,000 member Monte Carlo ensemble are used  
41 to derive the future ERFs from aerosols, contrails (and aviation-induced cirrus) and black carbon on snow,  
42 using the SSP emissions projections.

43  
44 Future ozone forcing for SSP projections differs from the historical treatment and is based on emissions of  
45 short-lived forcers and concentrations of ozone-depleting greenhouse gases (Section 6.4). To generate the  
46 best-estimate projection, the historical time series in Skeie et al. (2020) is matched to emissions-driven  
47 estimates of ozone ERF from *AerChemMIP* models (Thornhill et al., 2021b), displayed in Table 7.SM.3 that  
48 sums to +0.37 W m<sup>-2</sup> for 1850 to 2014. There is a temperature-dependent feedback on ozone ERF of  $-0.037$   
49 W m<sup>-2</sup> °C<sup>-1</sup> for CMIP historical runs (this differs from the assessment in Section 6.4 of  $-0.064$  W m<sup>-2</sup> °C<sup>-1</sup>  
50 which is based on *abrupt4xCO2* experiments, as it includes the effects of the lightning NO<sub>x</sub> and BVOC  
51 feedbacks that act to reduce the magnitude of the temperature-ozone feedback (Thornhill et al., 2021a)). As  
52 five of the six Earth System Models run in Skeie et al. (2020) considered in the ERF ozone assessment were  
53 CMIP historical runs (all except Oslo-CTM3) and simulated the increase in historical GSAT over time, they  
54 implicitly included this feedback and as such the  $-0.037$  W m<sup>-2</sup> °C<sup>-1</sup> feedback it is subtracted from the  
55 transient ozone ERF in these five models, using GSAT time series assessed in Chapter 2, to produce a “zero-

1 feedback” estimate of ozone forcing from 1850 to 2014 of  $+0.47 \text{ W m}^{-2}$ . To apply the emissions precursors  
 2 to the overall time series, they are scaled by a factor of 1.27, derived from a ratio of the zero feedback  
 3 estimate from Skeie et al. (2020) to the best estimate from the sum of precursors from Thornhill et al.  
 4 (2021b) ( $0.47/0.37$ ) to produce radiative efficiencies for each species (Table 7.SM.3).  
 5  
 6

7 **[START TABLE 7.SM.3 HERE]**

8  
 9 **Table 7.SM.3:** ERF from ozone precursors in AerChemMIP experiments (Thornhill et al., 2021b), and radiative  
 10 efficiencies derived for emissions-based SSP pathways. The contributions for CO + NMVOC are not  
 11 separated in Thornhill et al. (2021b) so the ratio of CO : NMVOC from CMIP5 ACCMIP experiments  
 12 is used (Stevenson et al., 2013). “Concentrations” of ozone-depleting halocarbons (ODHs) are  
 13 expressed in equivalent effective stratospheric chlorine in ppt.  
 14

species	Contribution to ozone ERF 1850-2014, $\text{W m}^{-2}$ (Stevenson et al., 2013; Thornhill et al., 2021b)	Scale factor to reproduce 1850-2014 ozone ERF in Skeie et al. (2020), after subtracting temperature feedback	Radiative efficiency for ozone ERF
CH <sub>4</sub>	$+0.14 \pm 0.05$	1.27	$\beta_{\text{CH}_4} = 0.175 \pm 0.062 \text{ mW m}^{-2} \text{ ppb}^{-1}$
N <sub>2</sub> O	$+0.03 \pm 0.02$		$\beta_{\text{N}_2\text{O}} = 0.710 \pm 0.062 \text{ mW m}^{-2} \text{ ppb}^{-1}$
Ozone-depleting halocarbons (ODH)	$-0.11 \pm 0.10$		$\beta_{\text{ODH}} = -0.125 \pm 0.113 \text{ mW m}^{-2} \text{ ppt}^{-1}$
CO	$+0.07 \pm 0.06$		$\beta_{\text{CO}} = 0.155 \pm 0.131 \text{ mW m}^{-2} \text{ MtCO}^{-1} \text{ yr}$

NO <sub>x</sub>	$+0.20 \pm 0.11$		$\beta_{\text{NO}_x} = 1.797 \pm 0.983 \text{ mW m}^{-2} \text{ MtNO}_2 \text{ yr}^{-1}$
Sum	$+0.37 \pm 0.18$	$+0.47 \pm 0.24 \text{ W m}^{-2}$ (total ozone ERF)	

15  
 16 **[END TABLE 7.SM.3 HERE]**

17  
 18  
 19 The future ozone ERF is then derived as

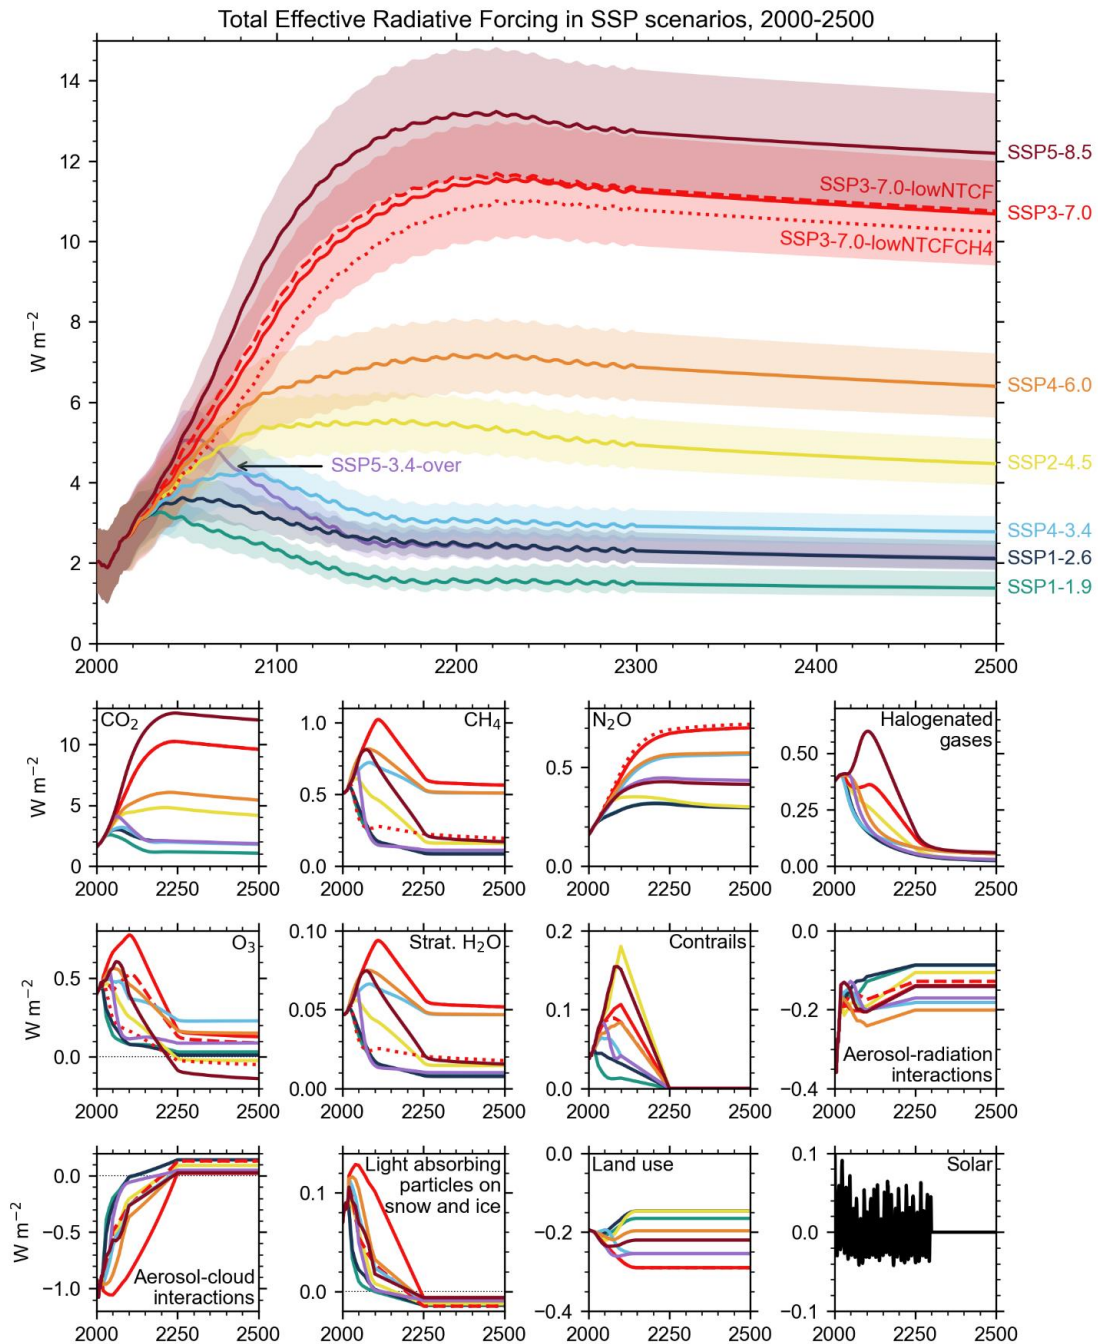

$$ERF_{\text{O}_3} = \beta_{\text{CH}_4} \Delta C_{\text{CH}_4} + \beta_{\text{N}_2\text{O}} \Delta C_{\text{N}_2\text{O}} + \beta_{\text{ODH}} \Delta C_{\text{ODH}} + \beta_{\text{CO}} \Delta E_{\text{CO}} + \beta_{\text{NMVOC}} \Delta E_{\text{NMVOC}} + \beta_{\text{NO}_x} \Delta E_{\text{NO}_x} - f \cdot \Delta T \quad \text{Equation 7.SM.1.3}$$

21 where  $C_{\text{CH}_4}$  and  $C_{\text{N}_2\text{O}}$  are concentrations of CH<sub>4</sub> and N<sub>2</sub>O in ppb,  $C_{\text{ODH}}$  is the equivalent effective  
 22 stratospheric chlorine from halogenated compounds expressed in ppt (Newman et al., 2007), and  $E_{\text{CO}}$ ,  
 23  $E_{\text{NMVOC}}$  and  $E_{\text{NO}_x}$  are annual emissions in Mt yr<sup>-1</sup> (NO<sub>x</sub> expressed in units of MtNO<sub>2</sub>),  $f = -0.037 \text{ W m}^{-2}$   
 24 °C<sup>-1</sup> and  $\Delta T$  represents GSAT anomaly. This configuration is run iteratively, with other best-estimate  
 25 forcings, in the two-layer emulator (Section 7.SM.2) with the Section 7.5.5 best-estimate assessments of  
 26 equilibrium climate sensitivity (ECS, 3.0°C) and transient climate response (TCR, 1.8°C) until convergence  
 27 is achieved.  
 28

29 ERF from land use change scales with cumulative emissions of land-use-related CO<sub>2</sub> emissions following the  
 30 end of the historical period.

1  
 2 Volcanic forcing is set to a ten-year linear ramp down to zero from 2014 to 2024, following the CMIP6  
 3 ScenarioMIP protocol (Eyring et al., 2016). Solar forcing uses the CMIP6 future TSI variation (Matthes et  
 4 al., 2017) which provides projections to 2299, and is set to zero from 2300. For Figure 4.36 and Annex III,  
 5 ERF time series for the RCP scenarios are produced using emissions and concentrations from Meinshausen  
 6 et al. (2011b) using the same methods, present-day forcing best estimates, and uncertainty ranges described  
 7 above, with the difference that scenarios start to diverge in 2005 and a 15-year ramp from 2005 to 2020 from  
 8 historical emissions or concentrations to the future RCP projections is performed.

 15 shown for SSP3-7.0-lowNTCF and SSP3-7.0-NTCFCH4 for visual clarity. Bottom matrix shows the

best estimate ERF for each anthropogenic component, and solar (volcanic ERF is zero beyond 2024).  
**[END FIGURE 7.SM.1 HERE]**

## 7.SM.2 Two-layer energy balance model for climate emulation

### 7.SM.2.1 Emulator definition

The two-layer emulator is based on the following global mean equations:

$$C \frac{d}{dt} \Delta T = \Delta F(t) + \alpha \Delta T - \varepsilon \gamma (\Delta T - \Delta T_d)$$

Equation 7.SM.2.1

$$C_d \frac{d}{dt} \Delta T_d = \gamma (\Delta T - \Delta T_d)$$

where  $\Delta T$  (°C) is the temperature of the surface layer (representing the surface components of the climate system),  $\Delta T_d$  (°C) is the temperature change in the deep ocean layer,  $C$  and  $C_d$  are the effective heat capacities for the surface and deep layers in  $\text{W yr m}^{-2} \text{°C}^{-1}$ ,  $\varepsilon$  is the efficacy of the deep ocean heat uptake and  $\gamma$  is the heat transfer coefficient between the surface and deep layer ( $\text{W m}^{-2} \text{°C}^{-1}$ ).

The analytical solution of Eq. (7.SM.2.1) is expressed by a combination of fast and slow modes with the decay time scales of  $\tau_f$  and  $\tau_s$ . For a given value of ECS, TCR is obtained as

$$\text{TCR} = \text{ECS} \left\{ 1 - \frac{1}{t} \left[ \tau_f a_f \left( 1 - e^{-\frac{t_0}{\tau_f}} \right) - \tau_s a_s \left( 1 - e^{-\frac{t_0}{\tau_s}} \right) \right] \right\}. \quad \text{Equation 7.SM.2.2}$$

The TCR is equal to  $\Delta T$  at year  $t = t_0 = 70$  in response to the forcing  $\Delta F$  increasing at a rate of 1% per year, and all parameters ( $\tau_f$ ,  $\tau_s$ ,  $a_f$ , and  $a_s$ ) can be calculated using  $C$ ,  $C_d$ ,  $\gamma$ ,  $\varepsilon$  and the net feedback parameter  $\alpha$  (the formulae are presented in Geoffroy et al. (2013a)). As discussed in Jiménez-de-la-Cuesta and Mauritsen (2019), TCR can also be estimated directly from the two-layer model parameters as  $\text{TCR} = \Delta F_{2 \times \text{CO}_2} / (-\alpha + \kappa)$ , where  $\kappa = \varepsilon \gamma$ .

The two-layer model can be calibrated to emulate the climate response of individual CMIP models (Geoffroy et al., 2013b, 2013a) using *abrupt4xCO2* experiments. Calibrations are performed for 44 CMIP6 models resulting in parameter estimates (mean and standard deviation) of  $C = 8.1 \pm 1.0 \text{ W yr m}^{-2} \text{°C}^{-1}$ ,  $C_d = 110 \pm 63 \text{ W yr m}^{-2} \text{°C}^{-1}$ ,  $\gamma = 0.62 \pm 0.13 \text{ W m}^{-2} \text{°C}^{-1}$ ,  $\varepsilon = 1.34 \pm 0.41$ ,  $\kappa = 0.84 \pm 0.38 \text{ W m}^{-2} \text{°C}^{-1}$ . Representative values from CMIP6 models in Eq. (7.SM.2.2) are  $\tau_f = 4.6 \text{ yr}$ ,  $\tau_s = 333 \text{ yr}$ ,  $a_f = 0.541$ ,  $a_s = 0.459$ .

### 7.SM.2.2 Constrained emulator ensemble

In several places in Working Group I (Chapter 1, Figure 7.7, Figure 7.8, Chapter 9), a constrained ensemble of two-layer model projections is used. The starting point for this ensemble is a 1 million-member ensemble of emissions-driven historical runs using v1.6.2 of the FaIR emulator (Millar et al., 2017; Smith et al., 2018a). The temperature module of FaIR is mathematically equivalent to the two-layer emulator in Eq. (7.SM.2.1), and the emissions- or concentrations-to-ERF relationships in FaIR are equivalent or very similar to those described in generating the ERF time series in Section 7.SM.1. The similarity of the two-layer model to FaIR is demonstrated in Figure 7.SM.2.

The 1 million ensemble members sample the uncertainty in the ERF, the climate response, and the carbon cycle. ERF uncertainties are generated using the same method described in Section 7.SM.1.3. For the climate response, the  $C$ ,  $C_d$ ,  $\gamma$  and  $\varepsilon$  components of the two-layer model in Eq. 7.SM.2.1 are generated from kernel-

1 density estimates that are calibrated to 44 CMIP6 models (Section 7.SM.2.1). The climate feedback  
 2 parameter  $\alpha$  is sampled from a truncated Gaussian distribution (truncated at  $\pm 2$  standard deviations) with  
 3 mean  $-1.33 \text{ W m}^{-2} \text{ }^{\circ}\text{C}^{-1}$  and standard deviation  $0.5 \text{ W m}^{-2} \text{ }^{\circ}\text{C}^{-1}$ . The carbon cycle in FaIR is parameterised by  
 4 the pre-industrial time-integrated airborne fraction of  $\text{CO}_2$ , and the change in airborne fraction with  
 5 accumulated carbon emissions and GSAT change (Millar et al., 2017). These parameters are sampled as  
 6 uniform distributions using the lowest and highest values based on calibrations to 11 CMIP6 models (Arora  
 7 et al., 2020) as the bounds of the distributions. The 1 million-member ensemble was run in the FaIR model  
 8 using emissions-driven runs from 1750 to 2019. The resulting ensemble was constrained based on agreement  
 9 to:

- 10 (1) the time series of historical GSAT to the Chapter 2 (Cross Chapter Box 2.3) assessment from 1850–  
 11 2020 with a root-mean-square error of  $0.135^{\circ}\text{C}$  or less, approximately recreating the headline 1850–  
 12 1900 to 1995–2014 assessment of  $0.67\text{--}0.98^{\circ}\text{C}$  (Cross Chapter Box 2.3, *very likely* range);
- 13 (2) the assessment of ocean heat uptake from Section 7.2.2.2 from 1971–2018 within the *likely* range of  
 14  $329\text{--}463 \text{ ZJ}$ ;
- 15 (3)  $\text{CO}_2$  concentrations to the 2014 *very likely* range of  $397.1 \pm 0.4 \text{ ppm}$  (Table 2.1);
- 16 (4) the airborne fraction from a 1% per year  $\text{CO}_2$  increase simulation to the range assessed in Section  
 17 5.5.1 of  $53 \pm 6\%$  (1 standard deviation).

18  
 19 From the original 1 million-member ensemble, 2,237 ensemble members passed all four constraints and are  
 20 used for reporting results. This constrained ensemble set from FaIRv1.6.2 has a good correspondence to  
 21 assessed ranges of key climate metrics across the Working Group I report (Cross Chapter Box 7.1 Table 1;  
 22 Table 7.SM.4). While not used as formal constraints, the assessed distributions of ECS and TCR (Section  
 23 7.5.2) and projected future warming from the five major SSP scenarios (Section 4.3.4) were used as  
 24 guidelines to ensure simultaneous adherence to several assessed ranges. As a comparison, the ECS from this  
 25 constrained set has a median and 5–95% ranges of ECS and TCR of  $2.95 [2.05 - 5.07]^{\circ}\text{C}$  and  $1.81 [1.36\text{--}$   
 26  $2.46]^{\circ}\text{C}$  respectively, compared to the Chapter 7 best estimates and *very likely* ranges of  $3.0 [2.0\text{--}5.0]^{\circ}\text{C}$  for  
 27 ECS and  $1.8 [1.2 - 2.4]^{\circ}\text{C}$  for TCR. While constraints (3) and (4) are not required when running FaIR or the  
 28 two-layer model using prescribed historical greenhouse gas concentrations, this 2,237 member ensemble set  
 29 is intended to be used to evaluate future warming pathways to integrated assessment model scenario  
 30 projections in Chapter 3 of Working Group III, so the same ensemble set is used here for overall consistency.  
 31  
 32

### 33 7.SM.2.3 Supporting information for Figures 7.7 and 7.8

34 The data contributing to Figures 7.7 and 7.8 is from the 2,237-member constrained ensemble described in  
 35 Section 7.SM.2.2. To provide the contributions to historical temperature in Figures 7.7 and 7.8, one of the 13  
 36 components of the historical forcing at a time is removed from the total forcing, and the two-layer model run  
 37 using the forcing and climate configuration from each of the 2,237 ensemble members. The difference  
 38 between the all-forcing and leave-one-out model run provides the temperature contribution from each  
 39 forcing agent. This exercise was repeated using a best-estimate climate response (hence, only assessing the  
 40 impact of uncertainty in the ERF) by setting  $\text{ECS} = 3.0^{\circ}\text{C}$ ,  $\text{TCR} = 1.8^{\circ}\text{C}$  and the other two-layer model  
 41 parameters set to their CMIP6 model means ( $C = 8.1 \text{ W yr m}^{-2} \text{ }^{\circ}\text{C}^{-1}$ ,  $C_d = 110 \text{ W yr m}^{-2} \text{ }^{\circ}\text{C}^{-1}$ ,  $\gamma = 0.64 \text{ W m}^{-2}$   
 42  $^{\circ}\text{C}^{-1}$  and  $\varepsilon = 1.36$ ; Section 7.SM.2.1). These simulations are shown as dashed error bars in Figure 7.7, with  
 43 the full ERF and climate response uncertainty as solid error bars.  
 44  
 45

46 Each ensemble member uses a long (approximately 9,000-year) pre-industrial spin-up comprising only  
 47 transient solar and volcanic forcing starting in 6755 BCE (Section 7.SM.1.3), and temperature changes are  
 48 reported with respect to 1750 as a single baseline year. The same 2,237 ensemble member set was extended  
 49 forward in time to 2500 under forcing from the SSP scenarios (Section 7.SM.1.4) and used to inform global-  
 50 mean sea level projections in Chapter 9.

1 **7.SM.3 Performance of emulators compared to key physical climate assessments**

2

3 Table 7.SM.4 details the performance of the four emulators (CICERO-SCM, FaIRv1.6.2, MAGICC7.5.1 and  
4 OSCARv3.1.1) described in Cross Chapter Box 7.1 for a number of climate assessments in absolute terms,  
5 and can be compared to Cross Chapter Box 7.1 Table 2 which details the relative difference between each  
6 emulator and the AR6 assessed range.

7

8

9

1 **[START TABLE 7.SM.4 HERE]**

2

3 **Table 7.SM.4:** Absolute differences between the emulator value and the Working Group I assessed best estimate and range for key climate assessments. Values are given for four  
 4 emulators in their respective AR6-calibrated probabilistic setups. Relative values of these indicators are shown in Cross Chapter Box 7.1, Table 2. Emulator values  
 5 within 5% of the assessed central value and 10% of the lower and upper ranges are unshaded, showing good correspondence between the emulator and the  
 6 assessment. The columns labelled “upper” and “lower” indicate *very likely* (5% to 95%) ranges, except for the variables demarcated with an asterisk or double  
 7 asterisk (\* or \*\*), where they denote *likely* ranges from 17% to 83%. Note that the TCRE assessed range (\*\*) is wider than the combination of the TCR and  
 8 airborne fraction to account for uncertainties related to model limitations.

9  
10 **Figure 7.SM.2:** (a) Time series and (b) 2100-2150 means of emulated GSAT projections from the Chapter 7 two-layer  
11 model (green), FAIRv1.6.2 (light blue), and MAGICC7.5.1 (orange) from 1995 to 2150, following the  
12 SSP1-2.6 scenario ((a) and (b)) and the SSP5-8.5 scenario ((c) and (d)). In (a) and (c) the ensemble  
13 median estimates are solid lines and the 5–95% ranges are shaded; in (b) and (d) the bar range shows  
14 5–95% ranges with the median in black. Overlaid CMIP6 model results are shown as lines in (a) and  
15 (c), and dots in (b) and (d) (fewer dots are shown for the 2100–2150 period because only a limited  
16 number of CMIP6 models have performed runs beyond 2100). In (a) and (c), Chapter 4 assessed  
17 GSAT projections (20-year running means) are shown with a dark blue dashed line and 5-95% range  
18 in dark blue shading.

## 7.SM.4 Equilibrium Climate Sensitivity and Transient Climate Response from CMIP6 models

Table 7.SM.5 details the equilibrium climate sensitivity and transient climate response estimated from CMIP6 and CMIP5 models using the ESMValTool (Eyring et al., 2020; Lauer et al., 2020; Righi et al., 2020) and presented in Schlund et al. (2020) for ECS and Meehl et al. (2020) for TCR (CMIP6 only), used in Section 7.5.6, Figure 7.18 and FAQ 7.3. Climate feedback parameters, including the decomposition into Planck, water vapour plus lapse rate, surface albedo and cloud components, plus the residual, are given for CMIP6 and CMIP5 models from Zelinka et al. (2020). ECS is estimated from a 150-year integration of an *abrupt4xCO2* experiment, subtracting the parallel *piControl* integration from the same period, regressing the modelled top-of-atmosphere energy imbalance  $\Delta N$  against the modelled GSAT change  $\Delta T$ , and taking  $\Delta T/2$  at the point where the regression slope crosses  $\Delta N = 0$  (Gregory et al., 2004). TCR is estimated from the mean  $\Delta T$  change from a *1pctCO2* run compared to the parallel *piControl* integration in years 60 to 79. Feedback contributions are estimated from a mean of six radiative kernels presented in Zelinka et al. (2020).

[START TABLE 7.SM.5 HERE]

**Table 7.SM.5:** Equilibrium climate sensitivity (ECS) and climate feedbacks estimated from CMIP5 and CMIP6 models. Transient climate response (TCR) from CMIP6 models is also provided. Data from Schlund et al. (2020), Meehl et al. (2020) and Zelinka et al. (2020).

14 Absolute Global Temperature-change Potential:

15

$$AGTP^X(H) = \Delta T^X(H) = \int_0^H AGFP^X(t) R_T(H-t) dt \quad \text{Equation 7.SM.5.3}$$

16 Absolute Global Sea-level Rise:

17

$$\begin{aligned} AGSR^X(H) &= \Delta SLR^X(H) = \int_0^H AGTP^X(t) R_{SLR}(H-t) dt \\ &= \int_0^H \int_0^t AGFP^X(t') R_T(t-t') R_{SLR}(H-t) dt' dt \end{aligned} \quad \text{Equation 7.SM.5.4}$$

18 where  $R_{SLR}$  is the sea-level rise resulting from a pulse temperature increase (Sterner et al., 2014).

19

20 Increase in absolute metric ( $\Delta AG_{XX}^X$ ) due to the carbon cycle response:

$$\Delta AG_{XX}^X = \int_0^H \int_0^t AGTP^X(t') \gamma r_F(t-t') AG_{XX}^{CO_2}(H-t) dt' dt \quad \text{Equation 7.SM.5.5}$$

21

22 where  $\gamma r_F(t)$  is the CO<sub>2</sub> flux perturbation following a unit temperature pulse in kgCO<sub>2</sub> yr<sup>-1</sup> K<sup>-1</sup> using the

1 parameterisation of Gasser et al. (2017b), and

2

$$r_F = \delta(t) - \frac{\alpha_1}{\tau_1} e^{-\frac{t}{\tau_1}} - \frac{\alpha_2}{\tau_2} e^{-\frac{t}{\tau_2}} - \frac{\alpha_3}{\tau_3} e^{-\frac{t}{\tau_3}} \quad \text{Equation 7.SM.5.6}$$

3

4 and the parameters used in Eqs. (7.SM.4.5) and (7.SM.4.6) are given in Table 7.SM.6.

5

6

7 **[START TABLE 7.SM.6 HERE]**

8

9 **Table 7.SM.6:** Parameters for the carbon cycle response function (from table 1 of (Gasser et al., 2017b)).

10

$\gamma$ (kgCO <sub>2</sub> yr <sup>-1</sup> °C <sup>-1</sup> )	$\alpha_1$	$\alpha_2$	$\alpha_3$	$\tau_1$ (yr)	$\tau_2$ (yr)	$\tau_3$ (yr)
$11.06 \times 10^{12}$	0.6368	0.3322	0.00310	2.376	30.14	490.1

11

12 **[END TABLE 7.SM.6 HERE]**

13

14

15 Metrics for step emission changes can be derived by integrating the more standard pulse emission changes

16 up to the time horizon:

17

$$AGTP_X^S = \int_0^H AGTP_X(H-t) dt \quad \text{Equation 7.SM.5.7}$$

18

19 The contribution to methane emission metrics from CO<sub>2</sub> from methane oxidation is given by

$$\Delta AG_{XX}^X = \int_0^H Y \frac{m_{CO_2}}{m_{CH_4}} \frac{1}{\tau_{OH}} e^{-\frac{(H-t)}{\tau_{OH}}} AG_{XX}^{CO_2}(H-t) dt \quad \text{Equation 7.SM.5.8}$$

20

21 where  $Y$  is the fractional molar yield of CO<sub>2</sub> from CH<sub>4</sub> oxidation (see Section 7.6.1.3),  $m_{CO_2}$  and  $m_{CH_4}$  are

22 the molar masses of CO<sub>2</sub> and CH<sub>4</sub>, and  $\tau_{OH}$  is the methane oxidation lifetime time to OH (9.7 yr; Section

23 6.3.1).

24

25

### 26 **7.SM.5.2 Impulse response functions for GTP and Chapter 6 calculations**

27

28 To generate a suite of two-layer configurations for uncertainty estimates in GTP calculations (Tables

29 7.SM.8–7.SM.13), information from the FaIRv1.6.2 and MAGICC7.5.1 AR6 calibration setups (Cross

30 Chapter Box 7.1) are used. FaIRv1.6.2 uses the two-layer model in Eq. (7.SM.2.1) as its core so converting

31 its parameters to two-layer configurations is trivial (discussed in Section 7.SM.2.2). To convert

32 MAGICC7.5.1's configuration to two-layer configurations, the two-layer model parameters are fitted to

33 MAGICC7.5.1's output from an abrupt 2×CO<sub>2</sub> experiment. However, such a fitting procedure produces only

34 an approximate translation because MAGICC7.5.1 is not well-represented by a two-timescale model. After

35 these two conversions are done an ensemble of two-layer configurations is generated which is used for

36 uncertainty analysis in GTP calculations.

37

38 To generate the Chapter 6 two-layer configuration, the timescales and efficacy parameters are calculated as

39 the average of FaIRv1.6.2's median and a fit to MAGICC7.5.1's median response (both in their AR6

40 calibrations). Response magnitudes that describe the contributions to the fast and slow response timescales

41 are calculated such that the Chapter 6 configuration matches the best-estimate ECS of 3.0°C and TCR of

42 1.8°C (Table 7.13) under the best-estimate ERF due to a doubling of CO<sub>2</sub> of 3.93 W m<sup>-2</sup>. This results in

43 parameter values for  $C = 7.7 \text{ W yr m}^{-2} \text{ °C}^{-1}$ ,  $C_d = 147 \text{ W yr m}^{-2} \text{ °C}^{-1}$ ,  $\alpha = -1.31 \text{ W m}^{-2} \text{ °C}^{-1}$ ,  $\varepsilon = 1.03$ ,  $\kappa =$

1 0.88 W m<sup>-2</sup> °C<sup>-1</sup>. Note these parameters differ from CMIP6 two-layer model calibrations in Section  
2 7.SM.2.1, as the set described here is derived from a constrained ensemble from two emulators.  
3  
4  
5

1 **7.SM.6 Tables of greenhouse gas lifetimes, radiative efficiencies and metrics**

2  
3 **[START TABLE 7.SM.7 HERE]**

4  
5 **Table 7.SM.7:** Greenhouse gas lifetimes, radiative efficiencies, Global Warming Potentials (GWPs), Global Temperature Potentials (GTPs) and Cumulative Global Temperature  
6 Potentials (CGTPs). GWPs given for 20-year, 100-year and 500-year time horizons. GTPs and CGTPs given for 50-year and 100-year time horizons. Note CGTP  
7 has units of years and is applied to a change in emission rate rather than a change in emission amount. Also shown are absolute values of GWPs and GTPs  
8 (AGWPs and AGTPs), in units of picowatt years per square metre per kilogram (1 pW = 10<sup>-12</sup> W). Radiative efficiencies for CH<sub>4</sub> and N<sub>2</sub>O given in this table do not  
9 include chemical adjustments (values including chemical adjustments are given in Table 7.15).

Name	Formula	Lifetime (yr)	Radiative efficiency (W m <sup>-2</sup> ppb <sup>-1</sup> )	AGWP 20 (pW m <sup>-2</sup> yr kg <sup>-1</sup> )	GWP 20	AGWP 100 (pW m <sup>-2</sup> yr kg <sup>-1</sup> )	GWP 100	AGWP 500 (pW m <sup>-2</sup> yr kg <sup>-1</sup> )	GWP 500	AGTP 50 (pW m <sup>-2</sup> yr kg <sup>-1</sup> )	GTP 50	AGTP 100 (pW m <sup>-2</sup> yr kg <sup>-1</sup> )	GTP 100	CGTP 50 (yr)	CGTP 100 (yr)

1 **[START TABLE 7.SM.8 HERE]**

2  
3 **Table 7.SM.8:** Estimated uncertainty in the GWP and GTP for CH<sub>4</sub> showing the total uncertainty as a percentage of  
4 the best estimate (expressed as 5-95% confidence interval), and the uncertainty by component of the  
5 total emission metric calculation (radiative efficiency, chemistry feedbacks, atmospheric lifetime, CO<sub>2</sub>  
6 (combined uncertainty in radiative efficiency and CO<sub>2</sub> impulse response), carbon cycle response, fate  
7 of oxidized fossil methane, and impulse-response function. Uncertainties in individual terms are taken  
8 from Section 7.6, except for the CO<sub>2</sub> impulse response which comes from (Joos et al., 2013). The  
9 impulse-response uncertainties are calculated by taking 1.645×standard deviation of the GTPs  
10 generated from 600 ensemble members of the impulse response derived from FaIRv1.6.2 and  
11 MAGICC7.5.1 (Section 7.SM.4.2)  
12
