Cross-Chapter Paper 4: Mediterranean Region
Supplementary Material

Cross-Chapter Paper Leads: Elham Ali (Egypt), Wolfgang Cramer (France)

Cross-Chapter Paper Authors: Jofre Carnicer (Spain), Elena Georgopoulou (Greece), Nathalie Hilmi (Monaco), Gonéri Le Cozannet (France), Piero Lionello (Italy)

Cross-Chapter Paper Contributing Authors: Ahmed Abdelrehim (Egypt), Mine Cinar (USA), Islam Abou El-Magd (Egypt), Shekoofeh Farahmand (Iran), François Gemenne (Belgium), Lena Reimann (Germany), Alain Safa (France), Sergio Vicente-Serrano (Spain), Francesca Spagnuolo (Italy), Duygu Sevilgen (Monaco), Samuel Somot (France), Rémi Thiéblemont (France), Cristina Tirado (USA), Yves Tramblay (France)

Cross-Chapter Paper Review Editors: Karim Hilmi (Morocco), Marta Rivera-Ferre (Spain)

Cross-Chapter Paper Scientist: Duygu Sevilgen (Monaco)

Date of Draft: 1 October 2021

Notes: TSU Compiled Version

### SMCCP4.1 Detection and Attribution of Climate Change Impacts in the Mediterranean Basin

Table SMCCP4.1: References supporting Figure CC4.5 (Attribution of observed impacts of climate change in the Mediterranean region).

<table>
<thead>
<tr>
<th>Impact</th>
<th>Supporting references</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thermal discomfort</td>
<td>Heatwaves are increasing due to climate change in the Mediterranean, and amplified in cities due to urbanization practices, ultimately increasing mortality and morbidity rates as well as energy consumption (<em>high agreement, robust evidence in the north, medium evidence in the south</em>) (WGI Chapters 10 and 12;WGII Chapters 9 and 13; Kuglitsch et al., 2010; Salvati et al., 2017; Zinzi and Carmelo, 2017; Pyrgou and Santamouris, 2018; Salameh et al., 2019; Maggiotto et al., 2021)</td>
</tr>
<tr>
<td>Pluvial and river flooding</td>
<td>There is a mixed signal of increasing and decreasing flood trends in the Mediterranean (Gaume et al., 2016; Blöschl et al., 2017; Gudmundsson et al., 2017; Kundzewicz et al., 2017; Siam and Eltahir, 2017), and there is <em>low confidence</em> in attribution to climate change due to the major impacts of human interventions such as land use change, groundwater exploitation, urbanization and non-optimal flood risk management (WGI Chapters 11 and 12 for extreme precipitation changes; Llasat et al., 2013; Mediero et al., 2014; Ziv et al., 2014; Baahmed et al., 2015; Polemio and Lonigro, 2015; Gaume et al., 2016; Llasat et al., 2016; Paprotny et al., 2018; Ribes et al., 2019; Tramblay et al., 2019; Vicente-Serrano et al., 2019; Argaman et al., 2020).</td>
</tr>
<tr>
<td>Water availability and quality</td>
<td>There is <em>high confidence</em> in detection and attribution of climate change impacts on water availability in the North-Western Mediterranean, and <em>medium confidence</em> in other subregions. There is emerging evidence on the impacts to water quality. (WGI Chapters 8 and 11; WGII Chapters 9 and 13; Hoerling et al., 2012; Ruffault et al., 2013; Vicente-Serrano et al., 2014; Aguilera et al., 2015; Quintana-Seguí et al., 2016; Van Vliet et al., 2016; Gosling et al., 2017; Spinoni et al., 2017; Calioero et al., 2018; Mathbou et al., 2018; Okkan and Kirdemir, 2018, Braca et al., 2019; Grillakis, 2019).</td>
</tr>
<tr>
<td>Wildfires</td>
<td>There is <em>medium confidence</em> that in Mediterranean Europe, wildfires are decreasing owing to good practices (Brotons et al., 2013; Turco et al., 2014; Turco et al., 2016), despite the increasing hazard caused by increased drought frequency and severity (WGI Chapter 11; Pausas and Fernández-Muñoz, 2012; Karafi et al., 2014; Fernández et al., 2016; Turco et al., 2017b; Ruffault et al., 2018). There is <em>low confidence</em> in any trends on wildfire for the south Mediterranean due to the lack of attribution studies, limited monitoring of direct human interventions and also limited fuel availability in the south east Mediterranean (Meddour-Sahar, 2015; Turco et al., 2017a; Curt et al., 2020).</td>
</tr>
<tr>
<td>Coastal flooding and erosion</td>
<td>Chronic flooding in Venice (Box 13.1) and generally Mediterranean extreme water levels during storms increase consistently with sea-level rise (Marcos et al., 2009). Flood and erosion hazards and risks have not been attributed to climate change yet, as they highly depend on coastal management strategies (WGI Chapter 13Frihy et al., 2010). Pocket beaches in the Mediterranean might be early responders to sea-level rise (Brunel and Sabatier, 2009). Some permanent flooding is observed in subsiding areas such as the region near Thessaloniki (Greece) (Raucoules et al., 2008).</td>
</tr>
<tr>
<td>Marine ecosystems</td>
<td>New evidence published since AR5 (AR5 WGII Chapters 5 and 18) confirms that a shift in Mediterranean marine ecosystems, characterized by biodiversity decline and invasive species, has occurred since the 1980s, with <em>high confidence</em> of a major climate change imprint superimposed with the impacts of human activities ( Chapter 3;Fortibuoni et al., 2015; Stergiou et al., 2016; Corrales et al., 2017; Givan et al., 2018; Azzurro et al., 2019; Kim et al., 2019; Albano et al., 2021).</td>
</tr>
<tr>
<td>Inland ecosystems</td>
<td>New evidence since AR5 WGII Chapter 18 confirms that terrestrial and freshwater ecosystems are impacted by climate change in the Mediterranean, resulting in loss of habitats and biodiversity and range shifts (e.g. birds), including through cascading impacts such as drought and wildfires (<em>high confidence</em> in northern Mediterranean, <em>medium confidence</em> in Southern Mediterranean) (Chapters 9 and 13 and CCP1; Stefanescu et al., 2011; Peñuelas et al., 2018; Bartsch et al., 2020).</td>
</tr>
</tbody>
</table>
Fisheries

New evidence published since AR5 WGII Chapter 18 (Sabatés et al., 2006; Lejeusne et al., 2010; Sabatés et al., 2012) further confirms that climate warming has had a negative impact on marine exploited fish stocks (high confidence), superimposed on the impacts of human activities such as overfishing. The economic value of proliferating species is generally less than that of declining species (high confidence) (Coll et al., 2014; Tsikliras and Stergiou, 2014; Stergiou et al., 2016; Azzurro et al., 2019).

Agriculture and viticulture

Changes in seasonality are attributed to climate change and the drying trends affect agriculture negatively (low confidence in the south-east Mediterranean and medium confidence in other sub-regions) (El-Maayar and Lange, 2013; Garcia-Mozo et al., 2015; Moore and Lobell, 2015; Oteros et al., 2015; Seif-Ennasr et al., 2016; Di Lena et al., 2018).

SMCCP4.2 Projected Climate Risks

The following tables provide the quantitative basis and literature references for the “burning ember” illustrations in Figure CCP4.8.

Table SMCCP4.2a: Supporting material for water availability and quality

<table>
<thead>
<tr>
<th>Risk with no/low adaptation</th>
<th>Range of temperature transition</th>
<th>Confidence level for transition</th>
<th>Explanation (text &amp; references)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undetectable to Moderate</td>
<td>0.8 – 1.0</td>
<td>High</td>
<td>• Increase of the fractional area under soil drought in the northern Mediterranean by 4-14% (Grillakis, 2019)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Reduction (median) in mean annual runoff in Spain by 5%, compared to 1980-2010 (Gosling et al., 2017)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Reduction of groundwater recharge in Italy by 7-12% from 1996-2015 (Braca et al., 2019)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Reduction of reservoir inflows in Turkey by 15% from 1980-2005 (Okkan and Kirdemir, 2018)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Change of gross hydropower potential by -5% up to +20% in the northern Mediterranean and by 5-60% in the southern Mediterranean, compared to 1971-2000 (Van Vliet et al., 2016)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Reduction of cooling water discharge capacity by 5-60%, from 1971-2000 (Van Vliet et al., 2016)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• The Standard Precipitation index (SPI) displays decreasing trends in the Mediterranean Basin (trends less clear in southern France). The typical characteristics of droughts (12-24 months SPI) mean that they have relevance for water management (Caloiero et al., 2018).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• The SPI (driven by precipitation) and SPEI (driven by precipitation and temperature) display remarkable drying trends in southern Europe, especially in summer and autumn during the last three decades, both in terms of frequency and intensity (Spinoni et al., 2017).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Increased severity of droughts in Spain attributed to higher evaporative demand due to rising temperatures (Vicente-Serrano et al., 2014)</td>

<tr>
<td>Moderate to High</td>
<td>1.4 – 2.0</td>
<td>High</td>
<td>• There is medium to high confidence that anthropogenic climate change increased drought severity in the Mediterranean (AR6 WGI Chapters 8 and 11)</td>
</tr>
</tbody>
</table>

- **High confidence** in increase of hydrological, agricultural and ecological droughts in the Mediterranean between 1.5 and 2°C of GWL (WGI Chapter 11).
- Aridity is projected to expand in the South Mediterranean (CCP3).
- Reduction of streamflow (90th percentile) by 12-16% in northern Mediterranean, compared to 1971-2000 (Marx et al., 2018).
- Reduction of average annual discharge in Spain by 14-37% from 1971-2000 (Marcos-Garcia et al., 2017) and by 13-14% from 2003-2013 in Italy (Pumo et al., 2016).
- Reduction (median) of mean annual runoff in Spain by 20% compared to 1980-2010 (Gosling et al., 2017) and of surface runoff in Turkey by 7-20% from 1970-2000 (Bucak et al., 2017).
- Reduction of low flows in France by 12% from 1980-2009 (Andrew and Sauquet, 2017) and by 15% or more over southern Europe (Roudier et al., 2016).
- Reduction of groundwater recharge in Italy by 10-18% from baseline (Masia et al., 2018; Braça et al., 2019).
- Reduction of reservoir inflows in Turkey by 21% from 1980-2005 (Okkap and Kirdemir, 2018) and of reservoir maximum water level by 14-31% from 1970-2000 (Bucak et al., 2017).
- Reduction of mean annual streamflow volume in Israel by 45-47% from 1996-2005 (Peleg et al., 2015).
- Reduction of water availability in southwestern Mediterranean by up to 40% from to 1976-2005 (Tramblay et al., 2018).
- Reduction of groundwater volume by 26-42% in a semi-arid catchment in Italy compared to baseline (Guyennon et al., 2017) and of groundwater availability in Greece by 12-18% from historic levels (Koutroulis et al., 2016).
- Reduction of hydropower production in Spain by 13-33% from baseline (Lobanova et al., 2016; Solaun and Cerdá, 2017), and by 10-20% on average over the entire Mediterranean (Turner et al., 2017).
- Reduction of gross hydropower potential by 60% or more from 1981-2000 (Van Vliet et al., 2016; Zhang et al., 2018).
- Reduction of available freshwater for cooling of thermal power plants by 6-18% from baseline in Spain and other northern Mediterranean locations (Payet-Burin et al., 2018; Tobin et al., 2018).
- In France, increase of area under risk of severe drought by 14-66% (EEA, 2017; Lozano et al., 2017; Peñuelas et al., 2017; Varela et al., 2019).
- Increase of the highest probability of four consecutive drought years by 20-82% compared to 1967-2016 (Lehner et al., 2017).
- Reduction of annual runoff by 9-37% (Schleussner et al., 2016; Sellami et al., 2016).

| High to Very High           | 2.7-3.2                         | High                           | Warming at 2.7-3.2°C:
- Reduction of hydropower production in Spain by 55% from baseline (Lobanova et al., 2016; Solaun and Cerdá, 2017).
- Reduction (median) of mean annual runoff in Spain by 20% compared to 1980-2010 (Gosling et al., 2017).
- Reduction (median) in groundwater water availability in Greece by 27% (Koutroulis et al., 2016). |
### Risk with no/low adaptation

<table>
<thead>
<tr>

</table>
| Undetectable to Moderate    | 0.8 - 1.5                       | Medium                          | - Reduction of streamflow (90\textsuperscript{th} percentile) by 35% in northern Mediterranean compared to 1971-2000 (Marx et al., 2018)  
- In Turkey, reduction (median) of surface runoff by 52% and reservoir maximum water level by 75-78% from 1970-2000 (Bucak et al., 2017)  
- Warming higher than 3.5°C:  
  - Very likely increase of hydrological, agricultural and ecological droughts in the Mediterranean at 4°C of GWL (WGI Chapter 11)  
  - In Italy, reduction of: a) groundwater volume by 57% in a semi-arid catchment compared to baseline (Guyennon et al., 2017), b) groundwater recharge by 42% from baseline (Braca et al., 2019), c) of average annual discharge by 32% from 2003-2013 (Pumo et al., 2016)  
  - Reduction of water availability in southwestern Mediterranean by up to 55% from 1976-2005 (Tramblay et al., 2018)  
  - Reduction of annual runoff in Portugal by 40-70% from 1961-1990 (Mourato et al., 2015)  
  - Reduction of annual discharge in Tunisia by 41-58% from 1970-2000 (Dakhlaoui et al., 2020)  
  - Reduction of surface runoff in Morocco by 55-63% from 1989-2009 (Marchane et al., 2017)  
  - Increase of the highest probability of four consecutive drought years by 220% compared to 1967-2016 (Lehner et al., 2017)  
  - Reduction of gross hydropower potential by 20-60% in northern Mediterranean and by 40-60% or more in southern Mediterranean from 1981-2000 (Van Vliet et al., 2016)  
  - Reduction of hydropower production in Spain by 30-55% from baseline (Lobanova et al., 2016; Solaun and Cerdà, 2017)  
  - Reduction of cooling water discharge capacity by more than 60% from 1971-2000 (Van Vliet et al., 2016)  

- Change of burnt area in northern Mediterranean by -5% to +54% (Wu et al., 2015; Turco et al., 2018)  
- In Italy, change of fire probability by -4.2% to +11.6%, of fire potential index by -5.5% to +11.8%, and of high flame length probability by -50% to +25% (EEA, 2017; Lozano et al., 2017; Peñuelas et al., 2017; Varela et al., 2019)  
- Wildfire hazard increasing due to increased drought frequency and severity (Pausas and Fernández-Muñoz, 2012; Karali et al., 2014; Fernandes et al., 2016; Turco et al., 2017b; Ruffault et al., 2018), but human interventions remain key driver of wildfire risk (Meddour-Sahar, 2015; Turco et al., 2017a; Curt et al., 2020), decrease of wildfire risk in the northern Mediterranean (Brotons et al., 2013; Turco et al., 2014; Turco et al., 2016)  
- Times of emergence of increased wildfire risk by the mid-21\textsuperscript{st} century in the north-western Mediterranean (Lozano et al., 2017)  

- Increase of areas prone to fire risk by 53% in Corsica (Garbolino et al., 2016)  
- Area with 7 or more days with extreme fire weather increasing by 82-217% in southern France (EEA, 2017; Lozano et al., 2017; Peñuelas et al., 2017; Varela et al., 2019)  
- Increase of fire risk in Turkey by 20% on average (Satir et al., 2016) |

---

| High to Very High           | 2.3 – 4.0                       | Medium                         | **2017; Brouziyne et al., 2018; Kheir et al., 2019.** Decrease of sunflower yield by 65% in Greece (Georgopoulou et al., 2017; Iocola et al., 2017).  
• Decrease of olive yield by 20% in Portugal (Fraga et al., 2020), by 3-8% in Italy (Fraga et al., 2020), by 19-21% in Spain (Fraga et al., 2020), and by 10-60% in Algeria (Bouregaa, 2019; Cammarano et al., 2019). Decrease of net primary production of olive groves by 0.02-11% in Italy (Brilli et al., 2019; Fraga et al., 2020).  
• Decrease of potato yield by up to -45% in northern Mediterranean (Zhao et al., 2015; Georgopoulou et al., 2017).  
• Decrease of various vegetable yields by 4-34% in Greece (Georgopoulou et al., 2017; Iocola et al., 2017).  
• Decrease of tomato yield by -19-81% over the entire Mediterranean (Saadi et al., 2015).  
• Apples at maturity in northeastern Spain could be of inferior quality, and chilling requirements may be unsatisfied (Funes et al., 2016; Rodriguez et al., 2019).  
• By 2060, more than 20% of exploited fishes and invertebrates currently found in eastern Mediterranean could become locally extinct (Jones and Cheung, 2015; Cheung et al., 2016; MedECC, 2020). High losses of clawed lobster production by the end of the century have also been projected under RCP4.5 (Boavida-Portugal et al., 2018). For much of the Mediterranean, fisheries' revenue may decrease by 15-30% by 2050 relative to 2000 under RCP8.5 (Lam et al., 2016).  
• Decrease of wheat yield by 5-59% in Algeria (Chourghal et al., 2016; Dettori et al., 2017; Iocola et al., 2017; Brouziyne et al., 2018; Bouregaa, 2019; Cammarano et al., 2019; Kheir et al., 2019), by 13-17% in Egypt, by more than 14% in Italy (Chourghal et al., 2016; Dettori et al., 2017; Iocola et al., 2017; Brouziyne et al., 2018; Kheir et al., 2019).  
• Decrease of barley yield by 22-29% in Algeria (Bouregaa, 2019; Cammarano et al., 2019).  
• Decrease of olive yield by 15-64% in Algeria (Bouregaa, 2019; Cammarano et al., 2019).  
• Change of tomato yield by -94% to +12% in Tunisia, depending on soil type and sowing date, or even non-viable crops under some combinations of soil type-sowing date (Bird et al., 2016),  
• In northeastern Spain, 28-72% of the years after 2070 could have winters not fulfilling chilling requirements for apple trees (Funes et al., 2016; Rodriguez et al., 2019), while chilling requirements will be severely compromised for other fruit trees in Spain (Funes et al., 2016; Rodriguez et al., 2019).  
• Early maturation may result in unbalanced wines through higher sugar and lower acids in the grape must after 2050 under RCP8.5 (Fraga et al., 2016; Koufos et al., 2018). Reduction in table quality vines and wine grape production in southern Europe due to a future increase in the cumulative thermal stress and dryness during the growing season (Cardell et al., 2019).  
• Net irrigation requirements for date palms in Tunisia under RCP8.5 are expected to increase by 34% in 2050 compared to 2018 to sustain date production (Haj-Amor et al., 2020).

<tr>
<td>Undetectable to Moderate</td>
<td>0.7-1.5</td>
<td>Medium</td>
<td>• Chronic flooding in Venice (Box 13.1)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Mediterranean extreme water levels during storms increase consistently with sea-level rise (Marcos et al., 2009).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Flood and erosion hazards and risks not attributed yet, highly depend on coastal management strategies (WGI Chapter 13; Frihy et al., 2010).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Pocket beaches in the Mediterranean might be early responders to sea-level rise (Brunel and Sabatier, 2009).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Some permanent flooding is observed in subsiding areas such as around Thessaloniki (Greece) (Raucoules et al., 2008).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Times of emergence of climate induced erosion after 2050 in Mediterranean beaches (Le Cozannet et al., 2016).</td>
</tr>
<tr>
<td>Moderate to High</td>
<td>1.5-2.0</td>
<td>High</td>
<td>• Multicriteria coastal risk analysis at the scale of the Mediterranean shows potential for high risks all around the basin, with more marked potential for high risk in the South-Eastern Mediterranean (Satta et al., 2017).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Chronic flooding taking place at high-tide significant concern in Venice (Box 13.1). The MOSE barrier will prevent such flooding, but the closure of the barrier is projected to reach 2 months per year with 50cm of sea-level rise, and adversely impacts ship traffic and lagoon water exchange (Box 13.1). Chronic flooding also projected to affect other low-lying areas in the Mediterranean such as the Ebro Delta (Sayol and Marcos, 2018), but a full picture of the problem is still missing at the scale of the Mediterranean.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Extreme water levels will change in response to two contrasting impacts of climate change in the Mediterranean: reduced storminess and increased or accelerating mean sea-level rise due to climate change, with the latter dominating over the farther by the mid-21st century (WGI Chapters 9 and 12; Lionello et al., 2017), possibly becoming the main driver of extreme changes e.g. in the North Western Mediterranean by 2050 (Le Cozannet et al., 2015; Sayol and Marcos, 2018).</td>
</tr>
<tr>
<td>High to Very High</td>
<td>2.0-2.8</td>
<td>High</td>
<td>• Hazards (e.g., extreme water levels amplification factors and allowances) and risks (e.g., economic average annual losses) projected to increase more quickly in the Mediterranean than in other regions of the world by 2050 (AR6 SROCC; Hallegatte et al., 2013), when GWL exceed 1.6 to 2.4°C (best estimate; AR6 WGI SPM).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Shoreline retreat caused by permanent flooding projected to become widespread in the Mediterranean for RCP8.5 by the mid century, or for RCP4.5 during the second half of the century, and further aggravates for higher levels of climate forcing (Snoussi et al., 2008; Le Cozannet et al., 2016; Antonioli et al., 2017; Anzidei et al., 2017; Ciro Aucelli et al., 2017; Enríquez et al., 2017; Jiménez et al., 2017; Antonioli et al., 2020). Storm surge superimposed with a rise of 0.5 m in mean sea-level could result in the loss of up to 90% of pocket beaches in the Aegean archipelago, at least temporarily (Monioudi et al., 2017). Sediment inputs from major rivers limited by upstream dams, reducing potential compensation of erosion by sediments (Besset et al., 2017).</td>
</tr>

<td>Operability times in ports, with shallower ports being projected to be more severely affected (Sierra et al., 2017). Groundwater salinization projected to increase with sea-level rise depending on the geological context and the processes through which aquifers are exploited and recharged. Sea-level rise not the only process causing salinization, but is projected to add another constraint to groundwater management and to sectors such as agriculture in a number of Mediterranean coastal floodplains and deltas, e.g., in some governorates of the Nile Delta for 1m of sea-level rise by 2100 (Mabrouk et al., 2018; Mastrocicco and Colombani, 2021; Pisinaras et al., 2021).</td>
</tr>
<tr>
<td>Moderate to High</td>
<td>1.2-1.5</td>
<td>Medium</td>
<td>Mediterranean sea-levels controlled by sea-level changes in the Atlantic through Gibraltar Strait at multi-decadal timescales (Calafat et al., 2012). Mediterranean sea-level projections are close to global trends (Thiéblemont et al., 2019) (see SMCCP4.4). Pre-industrial temperatures resulted in stable sea-level (AR5 WGI Chapter 13), whereas now recent greenhouse gas emissions have committed 0.7 to 1.1 m of sea-level rise by 2300 (AR6 WGI Chapter 9) (Nauels et al., 2019). Compared to other regions, the Mediterranean Region is characterized by a very high number of cultural heritage sites exposed to sea-level rises, some of which have been preserved since more than 2,000 years (Marzione and Levermann, 2014). To date, 37 Mediterranean UNESCO World Heritage sites are at risk from flooding, and 42 at risk of erosion (Reimann et al., 2018). This includes Venice, where high-tide flooding has increased consistently with relative sea-level changes (Box 13.1).</td>
</tr>
<tr>
<td>High to Very High</td>
<td>1.5-2.0</td>
<td>High</td>
<td>Sea-levels projected to rise between 0.3 to 3.1 m by 2300 for SSP1-2.6 (low confidence) (WGI, Chapter 9). Sea-level committed to rise by 2 to 3 m after 2,000 years, and by 6 to 7 m after 10,000 years for 1.5°C of GWL, but these long term projections incorporate processes in which there is low confidence (WGI, Chapter 9). The number of UNESCO World Heritage sites exposed to flooding (erosion) increases from 37 to 40 (from 42 to 46) for a sea-level rise of 1.2 m (“high-end scenario” based on Kopp et al., 2014) in (Reimann et al., 2018)). Flood frequencies, depths and erosion rates increase significantly in each of the cultural heritage sites already affected today (Reimann et al., 2018).</td>

The list of Northern Mediterranean countries (N) includes Bosnia and Herzegovina, Croatia, Cyprus, France, Greece, Italy, Malta, Monaco, Portugal and Spain. Southern Mediterranean countries (S) analysed are Algeria, Egypt, Jordan, Lebanon, Morocco, Syrian Arab Republic, Tunisia and Turkey.

Data extracted from (Sachs et al., 2019). All analyses reported significantly different mean SDG indicator values between N and S regions with p<0.0001 (Tukey-Kramer test).

SMCCP4.4 Mediterranean Sea-level Projections

Mediterranean sea-level projections presented in the FAQ are downscaled from those presented in AR6 WGI Chapter 9 and Technical Summary, following the method presented in Thiéblemont et al. (2019) (Table SMCCP4.4). Until 2100, the Mediterranean sterodynamic sea-levels are assumed to follow sterodynamic sea-level changes in the Atlantic near Gibraltar. The procedure ignores intra-basin sterodynamic sea-level changes, but it avoids biases due to the resolution of models and the coarse representation of water exchanges through the Gibraltar straight (Landerer et al., 2014; Meyssignac et al., 2017; Parras-Berrocal et al., 2020). Furthermore, observational evidence indicates that multi-decadal sea-level changes in the Mediterranean basin follow the Gibraltar forcing (Section 4.1; Calafat et al., 2012). Beyond 2150, Mediterranean sterodynamic sea-levels are assumed to follow the mean global thermal expansion.

Table SMCCP4.4: Mean sea-level projections in the Mediterranean relative to 1995-2014. There is medium confidence in the median values [likely range] shown for the five SSP scenarios. There is low confidence in the median values [17-83rd percentiles] shown for SSP5-8.5-L, a scenario based on a Structured-Expert Judgement or assuming marine ice-cliffs instabilities (See AR6 WGI Chapter 9 for details). Mediterranean projections include the mean Glacial Isostatic Adjustment in the Mediterranean, but not local vertical ground motions due to natural or anthropogenic processes such as tectonics or groundwater extractions.
