There are three levels at which policy attention on climate financing now may need to be focused. The first is the need to address the global equity issues in climate finance in a more carefully constructed globally cooperative public policy approach. The second is to address issues appropriately with enhanced support, at the national level. The third is to work it down further, to addressing needs at local community levels. Because private investors and financing mostly deal with allocation to climate finance at a global portfolio level, then to allocation by countries, and finally to individual projects, the challenge for them is to refocus attention to Just Transition issues at the country level, but also globally as well as locally (in other words, at all three levels).

Climate finance will likely face greater challenges in the post-pandemic context (Hanna et al. 2020; Henry et al. 2020). Evidence from the COVID-19 pandemic suggests that those in greatest vulnerability often had the least access to human, physical, and financial resources (Ruger and Horton 2020). It has also left in its wake divergent prospects for economic recovery, with rising constraints on credit ratings and costly debt burden in many developing countries contrasted with the exceptionally low interest rate settings in developed economies driving the limited fiscal space in the former groups (Benmelech and Tzur-Ilan 2020). Similarly, monetary policies are likely to be much tighter in developing countries in part structurally because of the absence of ‘exceptional privilege’ of global reserve currencies in developed economies.

The result is a divergence in recovery prospects in the aftermath of the pandemic, with output losses (compared to potential) set to worsen in developing economies (excluding China) as compared to developed

countries (IMF 2020b). In these circumstances, a coordinated and cooperative approach, instead of unilateralism, might work better (McKibbin and Vines 2020). In the case of climate, simulations clearly suggest the need and advantages of better coordinated climate action with stepped-up Paris Agreement envisaged transfers (IMF 2020b). Several options in international climate finance arrangements to support a Just Transition are both available and urgent.

As a first priority, measures might need to accelerate a mix of equitable financial grants, low-interest loans, guarantees and workable business models access across countries and borders, from developed countries to low-income countries. A big push on low-carbon energy access globally, especially in large low-income regions such as Africa, with accelerated financial transfers, makes sense (Boamah 2020). For about one billion people globally at the base of the pyramid without access to modern low-carbon energy access, such an action, with enormous immediate leap-frogging potential, would be a key pathway to achieve the SDGs, ensure that high-carbon energy use is avoided, such as the burning of biomass and forests for charcoal, and improve air quality and public health, especially women's health (van der Zwaan et al. 2018; Nathwani and Kammen 2019; Dalla Longa and van der Zwaan 2021; Michaelowa et al. 2021; Osabuohien et al. 2021).

A second priority is to accelerate the implementation of the USD100 billion a year (and likely more, given growing financing gaps) in climate finance commitments expressed in the Copenhagen Agreement Accord (and reiterated since) from developed to developing countries, and to build greater confidence by agreeing rapidly on key definitions. Shifting to a grant equivalent net flows definition of climate finance, which is now universally accepted for all other aid flows by all parties since 2014 and which took effect since 2019 on every other public international good finance provision (under the SDGs), with the sole exception of climate finance, would resolve many uncertainties: the disbursement of climate finance flows on a grant equivalent basis that is comparable across institutions, instruments and countries, and measurement with greater accuracy about the effective transfer of resources. The journey to get to a clear and precise definition of net official overseas development assistance (ODA) took time. The original proposal was first initiated in the 1960s (Pincus 1963) but it was not till multilateral development banks (MDBs) and others laid out the compelling reasons why (Chang et al. 1998) that this was accomplished: especially to resolve decades of confusion and inconsistency between different types of financial flows and hence the perennial measurement problems and 'the compromise between political expediency and statistical reality' (Bulow and Rogoff 2005; Hynes and Scott 2013; Scott 2015, 2017).

A third related and increasingly crucial priority is to expedite the operational definition of blended finance and promote the use of public guarantee instruments. Private flows to accelerate the low-carbon transition in developing countries would benefit enormously, by gaining clearer access to public international funds and support defined on a grant equivalent basis, provided development and climate finance operational definitions and procedures were improved on an urgent basis (Blended Finance Taskforce 2018a; OECD-DAC 2021). When blended and supported by public finance and policy, the grant

equivalency measure can easily and more accurately measure the value and benefit of blended public and private finance by comparing the effective interest cost (and volume) gain with such financing, against the benchmark costs without such blending. Here again, a pressing challenge is to improve the operational definitions of what counts as ODA within blended finance. Blended finance remains very poorly defined and accounted (Pereira 2017; Andersen et al. 2019; Attridge and Engen 2019; Basile and Dutra 2019). Guarantees are expressly not included in the definition of ODA (Garbacz et al. 2021). As a result, bilateral and multilateral agencies have no incentive or limited authority and basis to use such instruments, while multilateral development banks continue to approach guarantees with great caution because of the limits of their original charters (World Bank 2009) and require counter-indemnities by recipient countries, internal and historic agency inertia, perceived loss of control over the use of funds (compared to their preferred direct project-based lending) and employ restrictive accounting rules for capital provisioning of guarantees at 100% of their face value to maintain AAA ratings with credit rating agencies (Humphrey 2017; Pereira dos Santos and Kearney 2018; Bandura and Ramanujam 2019; Hourcade et al. 2021a). Largely because of such official uncertainty the actual flows of blended finance and guarantees continue to remain a very small share (typically, less than 5%) of official and multilateral finance flows to lower project risks and costs, and hence the potential for large-scale accelerated low-carbon private investments in developing countries. Public guarantees can offer a fifteen times multiplier effect on the scale of low-carbon investments generated with such support, compared to a 1:1 ratio in direct financing (Hourcade et al. 2021a).

It makes sense to expedite these operational procedures (Khan et al. 2020) which cannot be otherwise explained except in terms of avoiding responsibilities, even where the benefits would be high (Klöck et al. 2018). It also causes (unnecessary) fragmentation and complexity and often 'strategic' ambiguity by many actors (Pickering et al. 2017), which worsens the possibilities for international cooperation, a critical requirement to achieve the Paris goals (IPCC 2018). The world would gain collectively if these issues were to be decided soon. The absence of such a collective decision continues to be exceptionally costly for the implementation of the Paris Agreement because of the fractious and seemingly insoluble negotiating climate and a breakdown of trust that this has created (Roberts and Weikmans 2017).

A fourth priority is expanding jobs and dealing with job losses in the global low-carbon transition (Carley and Konisky 2020; Crowe and Li 2020; Pai et al. 2020; Cunningham and Schmillen 2021; Hanto et al. 2021), especially in coal and other sectors, as well as land and other effects for indigenous communities (Zografos and Robbins 2020). Many countries, especially low-income countries, remain dependent on fossil fuels for their energy and exports and jobs, and support for their transition to a low-carbon future will be essential. Global recovery from the pandemic will take longer than initially envisaged (IMF 2021c; OECD 2021b) and an accelerated climate action for a Build Back Better global infrastructure plan with better and more resilient jobs might play a key role as part of the Just Transitions. Already, there is substantial evidence (Sulich et al. 2020; Dell'Anna 2021; Dordmond et al. 2021) that a more sustainable climate path would generate many more net productive jobs (with much higher

employment multipliers and mutual gains from given spending) than would any other large-scale alternative. But this would nevertheless require a carefully managed transition globally, including access to much larger volumes of climate financing in developing economies (Muttitt and Kartha 2020). The multilateral finance institutions have generally played a supportive role, expanding their financing to developing countries during the pandemic (even as bilateral aid flows have fallen sharply), but have been hampered by the constraints on their mandates and instruments (as noted earlier). Political leadership and direction will be again crucial to enhance their roles. The recent expansion of SDR quotas at the IMF similarly might help, but the current distributions of quota benefits flow primarily to the developed countries and do little to expand investment flows on a longer-term basis for a global expansion in growth and job opportunities in the low-carbon transition.

As a fifth priority, transformative climate financing options based on equity and global sustainability objectives may also need to consider a greater mix of public pricing and taxation options on the consumption side (Arrow et al. 2004; Folke et al. 2021). Two-thirds of global GHG emissions directly or indirectly are linked to household consumption, with average per capita carbon footprint of North America and Europe of 13.4 and 7.5 tCO₂-eq per capita, respectively, compared to 1.7 in Africa and Middle East (Gough 2020) and as high as 200 tCO₂-eq per capita among the top 1% in some high-income geographies versus 0.1 tCO₂-eq at the other end of the income distribution in some least-developed countries (Chancel and Piketty 2015). Globally, the highest-expenditure households account for eleven times the per capita emissions of lowest-expenditure households, with rising carbon income elasticities that suggest 'redistribution of carbon shares from global elites to global poor' as welfare efficient (Chancel and Piketty 2015; Hubacek et al. 2017). Within countries and regions, and within sectors, similar patterns hold. The top 10% of the population with the highest per capita footprints account for 27% of the EU carbon footprint, and the top 1% have a carbon footprint of 55 tCO₂-eq per capita, with air transport the most elastic, unequal and carbon-intensive consumption (Ivanova and Wood 2020). Similarly, within sectors, there are large differences in carbon-intensity in the building sector in North America (Goldstein et al. 2020) and across cities where consumption-based GHG emissions vary widely across the world (ranging from 1.8 to 25.9 tCO₂-eq per capita).

Numerous options exist (Broeks et al. 2020; Nyfors et al. 2020) for such carbon consumption reduction measures, while potentially improving societal well-being, for example: (i) inner-city zoning restrictions on private cars and promoting walking/bicycle use and improved shared low-carbon transport infrastructure; (ii) advertising regulation and carbon taxes and fees on high-carbon luxury status goods and services; (iii) subsidies and exemptions for low-carbon options, higher value-added taxes on specific high-carbon products and services, subsidies for public low-carbon options such as commuter transport, and other behavioural nudges (Reisch et al. 2021); and (iv) framing options (emphasising total cost of car over lifetimes), mandatory smart metering, collective goods and services (leasing, renting, sharing options) and others. Finally, reducing subsidies on fossil fuels, raising the progressivity of taxes and raising overall wealth taxes on

the richest households, which have been sharply falling (Scheuer and Slemrod 2021) even as global income and wealth have risen, with regressive and falling overall taxes (Alvaredo et al. 2020; Saez and Zucman 2020), could effectively generate significant revenues (over 1% of GDP yr⁻¹), about the same size as the proposed global USD50 per tonne carbon price proposed and estimated by the IMF/OECD 2021 report to the G20 (IMF and OECD 2021) to cover expected net interest costs on overall decarbonisation initiatives and financing of green new deals (Schroeder 2021).

These five options identified above on near-term actions and priorities will however, require greater collective political leadership. A review of past crisis episodes suggests that collective actions to avoid large global or multi-country risks work well primarily when the problems are well defined, a small number of actors are involved, solutions are relatively well established scientifically, and public costs to address them are relatively small (Sandler 1998, 2015) (for example, dealing with early pandemic outbreaks such as Ebola, TB, and cholera; extending global vaccination programmes such as smallpox, measles and polio; early warning systems and actions for natural disasters such as tsunamis, hurricanes/cyclones and volcanic disasters; the Montreal Protocol for ozone-depleting refrigerants, and renewables wind and solar energy development). They do not appear to work as well for more complex global collective action problems which concern a number of economic actors, sectors, without inexpensive and mature technological options, and where political and institutional governance is fragmented. Greater political coordination is needed because the impacts are often not near term or imminent, but diffuse, slow moving and long term, and where preventive disaster avoidance is costly even when these costs are low compared to the longer-term damages – till tipping points are reached of the need for reduced 'stressors' and increasing 'facilitators' (Jagers et al. 2020). But by then, it may be too late.

Private institutional investors equally might equally wish to pay greater attention to the Just Transition finance issues. It would be useful for investors to identify ways to support to such initiatives, and more clearly identify the benefits of such transition measures envisaged by both countries and investment financing proposals, including incorporating Just Transition consideration in their support to broader ESG and green financing initiatives.

The second level of attention needed on Just Transitions has to do with inequities within a large country setting, developed or developing. The Just Transition issue exists within developed countries as well. As the ongoing pandemic illustrates, the first climate burden hit is often felt most acutely at the level of states and cities, with many smaller ones without enough fiscal capacity or ability to mount an adequate discretionary counter policy. Only national governments have the ability to borrow more in their fiscal accounts to address large collective problems, whether pandemics or climate change. Therefore, it is important that national policies and funds be available for programmes to address the Just Transition issues for larger subnational states, cities and regions. This would be helped by countries including Just Transition initiatives in their NDCs for financing (as South Africa has recently done), and attention by external financing agencies and MDBs to large-scale adverse impacts

in their climate policies and investments. For example, the EU Green Deal plans (Nae and Panie 2021) include several initiatives (focusing on industries, regions and workers adversely affected, with explicit programmes to address them).

The third level of argument is for a shift in focus from an exclusive attention to financing of mitigation and low-carbon new investments projects to also better understanding and addressing the local adverse impacts of climate change on communities and people, who are vulnerable and increasingly dispossessed due to losses and damages from climate change or even those who are impacted by decarbonisation measures in the fossil fuel sectors and transportation, as well as those who are harmed by polluting sectors: indigenous men and women, minorities and generally the poor. It is evident that very few resources are available to countries, investors, civil society, and smaller development institutions seeking to achieve a just transition (Robins and Rydge 2020).

Finally, greater support is warranted for smaller towns and cities, local networks, small and medium-sized enterprises (SMEs), communities, local authorities and universities for projects, research ideas and proposals (Lubell and Morrison 2021; Moftakhari et al. 2021; Stehle 2021; Vedeld et al. 2021).

15.3 Assessment of Current Financial Flows

15.3.1 Financial Flows and Stocks: Orders of Magnitude

Assessments of finance for climate action need to be placed within the broader perspective of all investments and financing flows and stocks. This section provides aggregate level reference points of relevance to the remainder of this chapter, notably when assessing current levels of climate and fossil fuel-related investments and

financing (Sections 15.3.2.3 and 15.3.2.4 respectively), as well as estimates of investment and financing needed to meet climate objectives (Section 15.4).

Measures of financial flows and stocks provide complementary and interrelated insights into trends over time: the accumulation of flows, measured per unit of time, results in stocks, observed at a given point in time (IMF 2009; UN and ECB 2015). On the flows side, GDP, a System of National Accounts (SNA) statistical standard that measures the monetary value of final goods and services produced in a country in a given period of time. In 2020, global GDP represented above USD₂₀₁₅ 70 trillion⁶ (down from around 80 trillion USD₂₀₁₅ in 2019), out of which developed countries represented approximately 60% (Figure 15.1); a slowly decreasing share over the last years. The GDP metric is useful here as an indicator of the level of activity of an economy but gives no indication relating to human well-being or SDG achievements (Giannetti et al. 2015) as it counts positively activities that negatively impact the environment, without making deductions for the depletion and degradation of natural resources.

Gross-fixed capital formation (GFCF), another SNA standard that covers tangible assets (notably infrastructure and equipment) and intangible assets, is a good proxy for investment flows in the real economy. In 2019, global GFCF reached around 20 trillion USD₂₀₁₅ compared to around 14 trillion USD₂₀₁₅ in 2010, a more than 40% increase (Figure 15.2). Global GFCF represents about a quarter of global GDP, a relatively stable ratio since 2008. This share is, however, much higher for emerging economies, notably in Asia, which are building new infrastructure at scale. As analysed in Sections 15.4 and 15.5, infrastructure investment needs and gaps in developing countries are significant. How these are met over the next decade will critically influence the likelihood of reaching the Paris Agreement goals.

⁶ In the chapter, USD units are used as reported in the original sources in general. Some monetary quantities have been adjusted selectively for achieving comparability by deflating the values to constant USD₂₀₁₅. In such cases, the unit is explicitly expressed as USD₂₀₁₅.

Figure 15.2 | Financial flows – GFCF (trillion USD₂₀₁₅) by type of economy (left) and region (right). Note: Regional breakdown based on official UN country classification. GDP in trillion USD₂₀₁₅. Gross fixed capital formation (GFCF) includes land improvements (fences, ditches, drains, and so on); plant, machinery, and equipment purchases; and the construction of roads, railways, and the like, including schools, offices, hospitals, private residential dwellings, and commercial and industrial buildings. On the stock side, an increasingly significant portion of the growing value of financial capital (stocks in particular) may be disconnected from the value of underlying productive capital in the real economy (Igan et al. 2020). This trend, however, remains uneven between developed countries, most of which have relatively deep capital markets, and developing countries at different stages of development (Section 15.6.7). Bonds, a form of debt financing, represent a significant share of total financial assets. As of August 2020, the overall size of the global bond markets (amount outstanding) was estimated at approximately USD128.3 trillion, out of which over two thirds was from ‘supranational, sovereign, and agencies’, and just under a third from corporations (ICMA 2020b). As discussed later in the chapter, since AR5, an increasing number and volume of bonds have been earmarked for climate action but these still only represent less than 1% of the total bond market. As of end-2020, climate-aligned bonds outstanding were estimated at USD0.9 trillion (Giorgi and Michetti 2021), though already raising concerns in terms of both underlying definitions (Section 15.6.6) and risks of increased climate-related indebtedness (Section 15.6.1, 15.6.3).

From the perspective of climate change action, these orders of magnitude make it possible to highlight the relatively small size of current climate finance flows and relatively larger size of remaining fossil fuel-related finance flows (discussed in the following two sub-sections), as well as, more generally, the significant overall scale of financial flows and stocks that have to be made consistent with climate goals. These orders of magnitude further make it possible to put in perspective climate-related investment needs (Section 15.4) and gaps (Section 15.5).

15.3.2 Estimates of Climate Finance Flows

The measurement of climate finance flows continues to face similar definitional, coverage and reliability issues as at the time of AR5 and the Special Report on Global Warming of 1.5°C, despite progress made (more sources, greater frequency, and some definitional improvements) by a range of data providers and collators. Based on available estimates (Table 15.1 and Figure 15.3), flows of annual

Table 15.1 | Total climate finance flows between 2013 and 2020.

Source (type)	2013	2014	2015	2016	2017	2018	2019	2020

global climate finance are on an upward trend since AR5, reaching a high-bound estimate of USD681 billion in 2016 (UNFCCC 2018a), representing USD674 billion 2015. Latest available estimates indicate a drop in 2018 (Buchner et al. 2019) and a rebound in 2019 and 2020 (*medium confidence*) (Naran et al. 2021). Although not directly comparable in terms of scope, current climate finance flows remain small (approx. 3%) compared to the GFCF reference point introduced in Section 15.3.1, and need to be put in perspective with remaining fossil fuel financing (*medium confidence*) (Section 15.3.2.3).

At an aggregate level, in both developed and developing countries, the vast majority of tracked climate finance is sourced from domestic or national markets rather than cross-border financing (Buchner et al. 2019). This reinforces the point that national policies and settings remain crucial (Section 15.6.2), along with the development of local capital markets (Section 15.6.7).

Climate finance in developing countries remains heavily concentrated in a few large economies (*high confidence*), with Brazil, India, China and South Africa accounting for around one-quarter to more than a third depending on the year, a share similar to that represented by developed countries. Least-developed countries (LDCs), on the other hand, continue to represent less than 5% year-on-year (*medium confidence*) (BNEF 2019; Buchner et al. 2019). Further, the relatively modest growth of climate finance in developed countries is a matter of concern given that economic circumstances are, in most cases, relatively more amenable to greater financing, savings and affordability than in developing countries.

At a global level, the majority of tracked climate finance is assessed as coming from private actors (Buchner et al. 2019), although, the boundaries between private and public finance include significant grey zones (Box 15.2), which implies that different definitions could lead to different conclusions (Yeo 2019; Weikmans and Roberts 2019).

However, private investments in climate projects and activities often benefit from public support in the form of co-financing, guarantees or fiscal measures. In terms of financial instruments and mechanisms, debt as well as balance sheet financing (which can rely on both own resources and further debt) and project financing (combining a large debt portion and smaller equity portion) represent the lion's share. In this context, the rapid rise of climate-related bond issuances since AR5 (Giorgi and Michetti 2021) represents an opportunity for scaling up climate finance but also poses underlying issues of integrity (Nicol et al. 2018a; Shishlov et al. 2018) and additionality (Schneeweiss 2019), as further discussed in Section 15.6.5, and needs to be considered in the context of overall indebtedness and debt sustainability (Sections 15.6.1 and 15.6.3).

Mitigation continues to represent the lion's share of global climate finance (consistently above 90% between 2017 and 2020), and in particular renewable energy, followed by energy efficiency and transport (*high confidence*) (UNFCCC 2018a; Buchner et al. 2019). While capacity additions on the ground kept rising, falling technology costs in certain sectors (e.g., solar energy) has had a negative impact on the year-on-year trend that can be observed in terms of volumes of climate finance (BNEF 2019; IRENA 2019a). However, such cost reduction could free up investment and financing capacities for potential use in other climate-related activities.

Tracking adaptation finance continues to pose significant challenges in terms of data and methods. Notably, the mainstreaming of resilience into investments and business decisions makes it difficult to identify relevant activities within financial datasets (Agrawala et al. 2011; Brown et al. 2015; Avershenkova et al. 2016). Despite these limitations, evidence shows that finance for adaptation remains fragmented and significantly below rapidly rising needs (Section 15.4 and Cross-Chapter Box FINANCE: Finance for Adaptation and Resilience in Chapter 17 of AR6 WGII report).

Box 15.4 | Measuring Progress Towards the USD100 Billion yr⁻¹ by 2020 Goal – Issues of Method

In 2009, at COP15, Parties to the UNFCCC agreed the following: ‘In the context of meaningful mitigation actions and transparency on implementation, developed countries commit to a goal of mobilising jointly USD100 billion a year by 2020 to address the needs of developing countries. This funding will come from a wide variety of sources, public and private, bilateral and multilateral, including alternative sources of finance’ (UNFCCC 2009).

This goal is further embedded as a target under SDG 13 Climate Action. While the parameters for what and how to count were not defined when the goal was set, progress in this area has been achieved under the UNFCCC (UNFCCC 2019b) and via a UN-driven independent expert review (Bhattacharya et al. 2020).

There remain well documented interpretations and debates on how to account for progress (Clapp et al. 2012; Stadelmann et al. 2013; Jachnik et al. 2015; Weikmans and Roberts 2019). Different interpretations relate mainly to the type and proportion of activities that may qualify as ‘climate’ on the one hand, and to how to account for different types of finance (and financial instruments) on the other hand. As an example, there are different points at which financing can be measured, for example, pledges, commitments, disbursements. There can be significant lags between these different points in time, for example disbursements may spread over time. Further, the choice of point of measurement can have an impact on both the volumes and on the characteristics (geographical origin, labelling as public or private) of the finance tracked. The enhanced transparency framework under the Paris Agreement may lead to improvements and more consensus in the way climate finance is accounted for and reported under the UNFCCC. Available analyses specifically aimed at assessing progress towards the USD100 billion goal remain rare, for example the UNFCCC SCF Biennial Assessments do not directly address this point (UNFCCC 2018a). Dedicated OECD reports provide figures based on accounting for gross flows of climate finance based on analysing activity-level data recorded by the UNFCCC (bilateral public climate finance) and the OECD (multilateral public climate finance, mobilised private climate finance and climate-related export credits) (OECD 2015a; OECD 2019a; OECD 2020b). For 2018, the OECD analysis resulted in a total of USD78.9 billion, out of which USD62.2 billion of public finance, USD2.1 billion of export credits and USD14.5 billion of private finance was mobilised. Mitigation represented 73% of the total, adaptation 19% and cross-cutting activities 8%.

Reports by Oxfam provide a complementary view on public climate finance, building on OECD figures and underlying data sources to translate gross flows of bilateral and multilateral public climate finance in grant equivalent terms, while also, for some activities, applying discounts to the proportion considered as climate finance (Carty et al. 2016; Carty and Le Comte 2018; Carty et al. 2020). The resulting annual averages for 2015–2016 and 2017–2018 range between 32% (low bound) and 44% (high bound) of gross public climate finance. The difference with OECD figures stems from the high share represented by loans, both concessional and non-concessional, in public climate finance, that is, 74% in 2018 (OECD 2020b).

A point of method that attracts much attention relates to how to account for private finance mobilised. The OECD, through its Development Assistance Committee, established an international standard to measure private finance mobilised by official development finance, which consists in methods tailored to different financial mechanisms. These methods take into account the role of, risk taken, and/or amount provided by all official actors involved in a given project, including recipient country institutions, thereby also avoiding risks of double counting (OECD 2019b). MDBs apply a different method (World Bank 2018a) in their joint climate finance reporting (AfDB et al. 2020), which neither correspond to the geographical scope of the USD100 billion goal, nor address the issue of attribution to the extent required in that context.

Notwithstanding methodological discussions under the UNFCCC, there is still some distance from the USD100 billion a year commitment being achieved, including in terms of further prioritising adaptation. While the scope of the commitment corresponds to only a fraction of the larger sums needed (Section 15.4), its fulfilment can both contribute to climate action in developing countries as well as to trust building in international climate negotiations. Combined with further clarity on geographical and sectoral gaps, this can, in turn, facilitate the implementation of better coordinated and cooperative arrangements for mobilising funds (Peake and Ekins 2017).

Further, there is increasing awareness about the need to better understand and address the interlinkages between climate change adaptation and disaster risk reduction (DRR) towards achieving resilience (OECD 2020a). Watson et al. (2015) however, note that between 2003 and 2014, of the USD2 billion that flowed through dedicated climate change adaptation funds, only USD369 million explicitly went to DRR activities (Climate Funds Update 2014; Nakhooda et al. 2014a; Nakhooda et al. 2014b; Watson et al. 2015). For the private sector, insurance and reinsurance remain the dominant way to transfer risk as discussed in Section 15.6.4).

More generally, significant gaps remain to track climate finance comprehensively at a global level:

- Available estimates are based on a good coverage of investments in renewable energy and, where available, energy efficiency and transport, while other sectors remain more difficult to track, such as industry, agriculture and land use (*high confidence*) (UNFCCC 2018a; Buchner et al. 2019).
- In contrast to international public climate finance, domestic public finance data remain partial despite initiatives to track domestic climate finance (e.g., Hainaut and Cochran 2018) and public expenditures (*high confidence*) (for instance based on the UNDP's Climate Public Expenditure and Institutional Review approach).

Data on private and commercial finance remain very patchy, particularly for corporate financing (including debt financing provided by commercial banks), for which it is difficult to establish a link with activities and projects on the ground (*high confidence*). Further, as individual sources of aggregate reporting (UNFCCC 2018a; Buchner et al. 2019; FS-UNEP Centre and BNEF 2020) tend to rely on the same main data sources (notably the BNEF commercial database for renewable energy investments) as well as to cross-check numbers against similar other sources, there is a potential for 'group-think' and bias.

Such data gaps as well as varying definitions of what qualifies as 'climate' (or more broadly as 'green' and 'sustainable') not only pose a measurement challenge. They also result in a lack of clarity for investors and financiers seeking climate-related opportunities. Such uncertainty can lead both to reduced climate finance as well as to a lack of transparency in climate-related reporting (further discussed in Section 15.6.1), which in turn further hinders reliable measurement.

In terms of finance provided and mobilised by developed countries for climate action in developing countries, while accounting scope and methodologies continue to be debated (Box 15.4), progress has been achieved on these matters in the context of the UNFCCC (UNFCCC 2019b). A consensus, however, exists, on a need to further scale up public finance and improve its effectiveness in mobilising private finance (OECD 2020b), as well as to further prioritise adaptation financing, in particular towards the most vulnerable countries (Carty et al. 2020). The relatively low share of adaptation in international climate finance to date may in part be due to a low level of obligation and precision in global adaptation rules and commitments (Hall and Persson 2018). Further, providers of international climate finance

may have more incentive to support mitigation over adaptation as mitigation benefits are global while the benefits of adaptation are local or regional (Abadie et al. 2013).

15.3.3 Fossil Fuel-related and Transition Finance

As called for by Article 2.1c of the Paris Agreement and introduced in Section 15.3.1, achieving the goal of the Paris Agreement of holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels requires making all finance consistent with this goal. Data on investments and financing to high GHG activities remain very partial and difficult to access, as relevant actors currently have little incentive or obligations to disclose such information compared to reporting on and communicating about their activities contributing to climate action. Further, the development of methodologies to assess finance for activities misaligned with climate mitigation goals, for hard- and costly-to-abate sectors such as heavy industries, as well as for activities that eventually need to be phased out but can play a transition role for a given period, remain work in progress. This results in limited empirical evidence to date.

In modelled pathways that limit warming to 1.5°C (>50%) with no or limited overshoot, however, make it clear that the share of fossil fuels in energy supply has to decrease (see Chapter 3). For instance, the International Energy Agency (IEA) Net Zero by 2050 scenario relies on halting sales of new internal combustion engine passenger cars by 2035, rapid and steady decrease of the production of coal (minus 90%), oil (minus 75%) and natural gas (minus 55%) by 2050, and phasing out all unabated coal and oil power plants by 2040 (IEA 2021b). To avoid locking GHG emissions incompatible with remaining carbon budgets, this implies a rapid scaling down of new fossil fuel-related investments, combined with a scaling up of financing to allow energy and infrastructure systems to transition (*high confidence*).

The IEA provides comprehensive analyses of global energy investments, estimated at about USD1.8 trillion a year over 2017–2019 (IEA 2019a, 2020a), and expected to reach that level again in 2021 after a drop to about 1.6 trillion in 2020 (IEA 2021c). Energy investments represent about 8% of global GFCF (Section 15.3.2.1). In the power sector, fossil fuel-related investments reached an estimated USD120 billion yr⁻¹ on average over 2019–2020, which remains well above the level that underpin the IEA's own Paris-compatible Sustainable Development Scenario (SDS) and Net Zero Emission (NZE) scenarios. The IEA observes a similar inconsistency for supply-side new investments: in 2019–2020 on average yr⁻¹, an estimated USD650 billion were invested in oil supply and close to USD100 billion in coal supply. These estimates also result in fossil fuel investments remaining larger in aggregate than the total tracked climate finance worldwide (Section 15.3.2.2). For oil and gas companies, which are amongst the world's largest corporations and sometimes government owned or backed, low-carbon solutions are estimated to represent less than 1% of capital expenditure (IEA 2020b). As discussed in the remainder of this chapter, shifting investments towards low-GHG solutions requires a combination of

conducive public policies, attractive investment opportunities, as well as the availability of financing to finance such a transition.

In terms of financing provided to fossil fuel investments, available analyses point out a still significant role played by commercial banks and export credit agencies. Commercial banks provide both direct lending as well as underwriting services, the latter facilitating capital raising from investors in the form of bond or share issuance. Available estimates indicate that lending and underwriting extended over 2016–2019 by 35 of the world's largest banks to 2100 companies active across the fossil fuel lifecycle reached USD687 billion yr^{-1} on average (Rainforest Action Network et al. 2020). Official export credit agencies, which are owned or backed by their government, de-risk exports by providing guarantees and insurances or, less often, loans. In 2016–2018, available estimates indicate the provision of about USD31 billion yr^{-1} worth of fossil fuel-related official export credits, out of which close to 80% was for oil and gas, and over 20% for coal (DeAngelis and Tucker 2020).

Finance for new fossil fuel-related assets lock in future GHG emissions that may be inconsistent with remaining carbon budgets and, as discussed above, with emission pathways to reach the Paris Agreement goals. This inconsistency exposes investors and asset owners to the risk of stranded assets, which results from potential sharp strengthening climate public policies, that is, transition risk. As a result, a growing number of investors and financiers are assessing climate-related risks with the aim to disclose information about their current level of exposure (to both transition and physical climate-related risks), as well as to inform their future decisions (TCFD 2017). Reporting to date is, however, inconsistent across geographies and jurisdictions (CDSB and CDP 2018; Perera et al. 2019), with also a wide variety of metrics, methodologies, and approaches developed by commercial providers that contribute to disparate outcomes (Kotsantonis and Serafeim 2019; Boffo and Patalano 2020). Further, as developed in Section 15.6.1, there is currently not enough evidence in order to conclude whether climate-related risk assessments result in increased climate action and alignment with the goals of the Paris Agreement (The 2° Investing Initiative and Wüest Partner 2020).

As developed in Section 15.6.3, the insufficient level of ambition and coherence of public policies at national and international levels remains the root cause of the still significant misalignment of investment and financing compared to pathways compatible with the Paris Agreement temperature goal (UNEP 2018). Such lack of coherence includes low pricing of carbon and of environmental externalities more generally, as well as misaligned policies in non-climate policy areas such as fiscal, trade, industrial and investment policy, and financial regulation (OECD 2015b), as further specified in the sectoral Chapters 6 to 12.

The most documented policy misalignment relates to the remaining very large scale of public direct and indirect financial support for fossil fuel-related production and consumption in many parts of the world (Bast et al. 2015; Coady et al. 2017; Climate Transparency 2020). Fossil fuel subsidies are embedded across economic sectors as

well as policy areas, for example, from a trade policy perspective, in most countries, import tariffs and non-tariff barriers are substantially lower on relatively more CO₂ intensive industries (Shapiro 2020). Available inventories of fossil fuel subsidies (in the form of direct budgetary transfers, revenue forgone, risk transfers, or induced transfers), covering 76 economies, indicate a rise to USD340 billion in 2017, a 5% increase compared to 2016. Such trend is due to slowed down progress in reducing support among OECD and G20 economies in 2017 (OECD 2018b) and to a rise in fossil fuel subsidies for consumption in several developing economies (Matsumura and Adam 2019), which, in turn, reduces the efficiency of public instruments and incentives aimed at redirecting investments and financing towards low-GHG activities.

As a result, the demand for fossil fuels, especially in the energy production, transport and buildings sectors, remain high, and the risk-return profile of fossil fuel-related investments is still positive in many instance (Hanif et al. 2019). Political economy constraints of fossil fuel subsidy reform continue to be a major hurdle for climate action (Schwanitz et al. 2014; Röttgers and Anderson 2018), as further discussed in Section 15.5.2. and Chapter 13.

15.4 Financing Needs

15.4.1 Definitions of Financing Needs

Financing needs⁷ are discussed in various contexts, only one being international climate politics and finance. Also, financing needs are used as an indicator for required system changes (when compared to current flows and asset bases) and an indicator for near- to long-term investment opportunities from the perspective of investors and corporates. Investment needs are widely used as an indicator focusing on initial investments required to realise new infrastructure. It compares relatively well with private sector flows dominated by return-generating investments but lacks comparability and explanatory power regarding the needs in the context of international climate cooperation, where considerations on economic costs play a more substantial role. Chapter 12 elaborates on global economic cost estimates for various technologies. This indicator includes both costs and benefits of options, of which investment-related costs make up only one component. Both analyses offer complementary insights. There are financing needs not directly related to the realisation of physical infrastructure and which are not covered in both investment and cost estimates. For instance, the needs for building institutional capacity to achieve social and economic goals and to strengthen knowledge, skills, national and international cooperation might not be significant, but an enabling environment for future investments would not be established without satisfying it. Moreover, comprehending financial needs for addressing economic losses due to climate change can hardly be measured in terms of the indicators introduced before.

Understanding the magnitude of the challenge to scale up finance in sectors and regions requires a more comprehensive (and qualitative)

⁷ The term Investment 'Needs' used in the chapter means equal to the term Investment Requirement used in SPM.

assessment of the needs. For finance to become an enabler of the transition, domestic and international public interventions can be needed to ensure enough supply of finance across sectors, regions and stakeholders. The location of financing needs and vicinity to capital matter given home bias (Fuchs et al. 2017; OECD 2017a; Ito and McCauley 2019) (prioritising own country or regions), transaction costs and risk considerations (Section 15.2). Most of the finance is mobilised domestically but the depth of capital markets is substantially greater in developed countries, increasing the challenges to mobilise substantial volumes of additional financing for many developing countries. The same applies to various stakeholders with limited connections into the financial sector. In addition, governments enabling financial market frameworks, guidelines and supportive infrastructure is crucial for inclusive finance for the bottom of the pyramid, especially disadvantaged and economically marginalised segments of society.

The attractiveness of a sector and region for capital markets depends on several factors. Some essential elements are the duration of loan and profile as long-term loans and heavily heterogeneous returns represent challenges in financing mitigation technologies and policies. After the financial crisis and restricted access to long-term debt, capital intensity of technologies and resulting long payback periods of investment opportunities for mitigation technologies have been a crucial challenge (Bertoldi et al. 2021). Also, implicit discount rates applied during the investment decision process vary depending on the payback profile, with research mainly covering the difference between the financing of assets generating revenues versus costs (Jaffe et al. 2004; Schleich et al. 2016). In addition, a low correlation between the climate projects and dominating asset classes might provide an opportunity in climate action by satisfying the appetite of institutional investors, which tend to manage portfolios with consideration of the Markowitz modern portfolio theory (optimising return and risk of a portfolio through diversification) (Marinoni et al. 2011). Transaction cost is a significant barrier to the diffusion and commercialisation of low-carbon technologies and business models and adaptation action. High transaction costs, attributed to various factors, such as complexity and limited standardisation of investments, limited pipelines, complex institutional and administrative procedures, create significant opportunity costs of green investments comparing with other standard investments (IRENA 2016; Nelson et al. 2016; Feldman et al. 2018). For example, transaction costs are commonly observed in small-scale, dispersed independent renewable energy systems, especially in rural areas, and energy efficiency projects (Hunecke et al. 2019). A more robust standardisation and alignment of Power Purchase Agreement (PPA) terms with best practices globally has led to a substantially increased interest in capital markets in developing countries (WBCSD 2016; Schmidt et al. 2019; World Bank 2021). Notably, PPA significantly increases the probability of more balanced investment and development outcomes and ultimately more sustainable independent power projects in developing countries. Therefore, lowering transaction costs would be essential for creating investor appetite. The role of intermediaries bundling demand for financing has been demonstrated to reduce transaction costs and to reach investors' critical size. In addition, new innovative approaches, such as fintech and blockchain (Section 15.6.8), have been discussed for providing new opportunities in the energy sector.

Economic viability of investments – ideally not relying on the pricing of positive externalities – has been a critical driver of momentum in the past. The falling technology costs and the competitiveness of renewable technologies, especially solar PV and wind, have accelerated the deployment of renewable technologies over the past years. Renewable energy technologies are now often competitive, and have even become the cheapest, in many countries, even without financial support (FS-UNEP Centre and BNEF 2015, 2016, 2017, 2018, 2019; IEA 2020c; IRENA 2020a) and without pricing of the avoided carbon emissions. In contrast, the dependency on regulatory interventions and public financial support to create financial viability has provided a source of volatile investor appetite. The annual volume of renewable investment by country is often volatile, reflecting ending and new regulations and policies (IEA 2019a).

For example, the recent Chinese policy direction towards tougher access to and a substantial cut in feed-in-tariffs in 2018 led to a significant drop in renewable investment and new capacity addition in China (FS-UNEP Centre and BNEF 2019; Hove 2020). However, the significant bouncing back of newly installed capacity (72 GW wind power and 47 GW solar power in 2020) shows the strong development of zero-carbon power generation driven by lower cost and policies to support them by energy revolution strategies in China. Investors had proven to be willing to work with transparent support mechanisms, such as with the Clean Development Mechanism (CDM), which stimulated emission reductions and allowed industrialised countries to implement emission-reduction projects in developing countries to meet their emission targets (Michaelowa et al. 2019). However, the collapse of carbon markets and prices, especially of the EU Emissions Trading System, led to the continuous decline of Certified Emission Reductions issuances from CDM in the past years (World Bank Group 2020). Also, the dependency on regulatory intervention to ensure fair market access only has proven to burden investor appetite.

A significant share of investment needs in heavily regulated sectors, such as electricity, public transport, and telecom, emphasises the importance of regulatory intervention, such as ownership and market access (OECD 2017b). For instance, energy-system developments require effective and credible commitments and action by policymakers to ensure an efficient capital allocation aligned with climate targets (Bertram et al. 2021).

There is a lot of discussion about the regulated ownership of the private sector (European Commission 2017) and the restructuring of electricity market contributed to low level of investment in baseline electricity capacity and in investment research and innovation. These changes create uncertainty of investment, and barriers to market entry and exit also potentially limit the competition in the market and restrict the entrance of new investment (Finon 2006; Joskow 2007; Grubb and Newbery 2018). This is also the case in developing countries (Foster and Rana 2020).

The positive development in the energy sector has benefitted from the evident stand-alone character of renewable energy generation projects. First movers realised these projects with investors and developers acting from conviction (Steffen et al. 2018). Such action is not possible to this extent in energy efficiency with related investment

rather representing an add-on component and consequently requiring the support of decision-makers used to business-as-usual projects. Despite the benefits that improvement of energy efficiency has in contributing to curbing energy consumption, mitigating greenhouse gas emissions, and providing multiple co-benefits (IEA 2014a), investment in energy efficiency is a low priority for firms, and the financial environment is not favourable due to lack of awareness of energy efficiency by financial institutions, existing administrative barriers, lack of expertise to develop projects, asymmetric information, and split incentives (UNEP DTU 2017; Cattaneo 2019). While Energy Service Companies' (ESCO) business models are expected to facilitate the investment in energy efficiency by sharing a portion of financial risk and providing expertise, there has been limited progress made with ESCO business models, and only slightly over 20% of projects used financing through ESCOs (UNEP DTU 2017).

The investment needs and existing challenges differ by sector. Each sector has different characteristics along the arguments listed above making the supply of finance by commercial investors an enabling factor or barrier. In the transport sector, transformation towards green mobility would provide significant co-benefits for human health by reducing transport-related air pollution, so the transport sector cannot achieve such transformation in isolation from other sectors. However, a considerable involvement of the public sector in many transportation infrastructure projects is given, and the absence of a standard solution increases transaction costs (including bidding package, estimating, drawing up a contract, administering the contract, corruption, and so on). Financial constraints, including access to adequate finance, pose a significant challenge in the agriculture sector, especially for SMEs and smallholder farmers. The distortion created by government failure and a lack of effective policies create barriers to financing for agriculture. The inability to manage the impact of the agriculture-related risks, such as seasonality, increases uncertainty in financial management. Moreover, inadequate infrastructure, such as electricity and telecommunication, makes it difficult for financial institutions to reach agricultural SMEs and farmers and increases transaction costs (World Bank 2016). Low economies of scale, low bargaining power, poor connectivity to markets, and information asymmetry also lead to higher transaction costs (Pingali et al. 2019). In the industrial manufacturing and residential sector, gaining energy efficiency remains one of the critical challenges. Investment in achieving energy efficiency encounters some challenges when it may not necessarily generate direct or indirect benefits, such as increase in production capacity or productivity and improvement in product quality. Also, early-stage, high upfront cost and future, stable revenue stream structure suggest the needs for a better enabling environment, such as a robust financial market, awareness of financial institutions, and regulatory frameworks (e.g., stringent building codes, incentives for ESCOs) (IEA 2014a; Barnsley et al. 2015).

15.4.2 Quantitative Assessment of Financing Needs

Multiple stakeholders prepare and present quantitative financing needs assessments with methodologies applied to vary significantly representing a major challenge for aggregation of needs (e.g., Osama et al. (2021) for African countries), most of them with a focus on

scenarios likely to limit warming to 2°C or lower. The differences relate to the scope of the assessments regarding sectors, regions and periods, top-down versus bottom-up approaches, and methodological issues around boundaries of climate-related investment needs, particularly full vs incremental costs and the exclusion or inclusion of consumer-level investments. Information on investment needs and financing options in NDCs mirrors this challenge and is heavily heterogeneous (Zhang and Pan 2016).

In particular, for global approaches, modelling assumptions are often heavily standardised, focusing on technology costs. Only limited global analysis is available on incremental costs and investments, reflecting the reality of developing countries, also considering the interplay with significant infrastructure finance gaps, and can hardly serve as a robust basis for negotiations about international public climate finance. The focus on investment irrespective of uncertainty as well as other qualitative aspects of needs does not allow for a straightforward analysis of the need for public finance to leverage private sector financing and of the country heterogeneity in terms of investment risks and access to capital (Clark et al. 2018).

One source of uncertainty about the investment estimates for the power sector is the evolution of the levelised cost of technical options in the future, for example the continuation of the observed declining costs trends of renewable energy (IRENA 2020b) which has been underestimated in many modelling exercises. The learning by doing processes and economies of scale might be at least partially outweighed, in all countries and more specifically in Small Island Developing States (SIDS) and other developing countries because of different risk factors, scales of installations, accessibility, and others (Lucas et al. 2015; van der Zwaan et al. 2018). These parameters, together with transaction costs/soft costs (Section 15.5), financing costs and the level of technical competences need to be better represented in the future to represent the 'climate investment trap' in many developing countries (García de Fonseca et al. 2019). This 'climate investment trap', as flagged by Ameli et al. (2021a), is created by existing and expected physical effects of climate change, higher financing costs and resulting lower investment levels in developing countries. Applying significantly standardised assumptions can consequently not provide robust insights for specific country groups. This will require progress in the spatiotemporal granularity of the models (Collins et al. 2016).

Another source of uncertainty about the financing needs is the interplays between (i) the baseline economic growth rates, (ii) the link between economic growth and energy demand, including rebound effects of energy efficiency gains, (iii) the evolution of microeconomic parameters such as fossil fuel prices, interest rates, currency exchange rates (iv) the level of integration between climate policies and sectoral policies and their efficacy, and (v) the impact of climate policies on growth and the capacity of fiscal and financial policies to offset their adverse effect (IPCC 2014; IPCC 2018). Integrated assessment models (IAMs) try to capture some of these interplays even though they typically do not capture the financial constraints and the structural causes of the infrastructure investment gap. Many of them rely on growth models with full exploitation of the means of production (labour and capital). They nevertheless provide useful

indications of the orders of magnitude at play over the long run, and the determinants of their uncertainty. Global yearly average low-carbon investment needs until 2030 for electricity, transportation, AFOLU and energy efficiency measures including industry and buildings are estimated between 3% and 6% of the world's GDP according to the analysis in Section 15.5. The incremental costs of low-carbon options are less than that and their funding could be achieved without reducing global consumption by reallocating 1.4% to 3.9% of global savings. 2.4% on average (see Box 4.8 of SR1.5 (IPCC 2018)) currently flow towards real estate, land and liquid financial vehicles. For the short-term decisions, the major information they give is the uncertainty range because this is an indicator of the risks decision-makers need.

While the AR6 Scenarios Database provides good transparency with regard to technology costs for electricity generation, assumptions driving in particular investments in energy efficiency are rarely made available in both IAM-based assessments and also other studies. Taking into account the much broader range of tested and untested technologies the confidence levels, in particular for 2050 estimates, remain low but can provide an initial indication. Also, the ranges allow for a rough indication on possible 'green' investment volumes and respective asset allocation for financial sector stakeholders.

Using global scenarios assessed in Chapter 3 for assessing investment requirements. Tables 15.2 and 15.3 present the analysis of investment requirements in global modelled mitigation pathways assessed in Chapter 3 for key energy sub-sectors within modelled global pathways that limit warming to 2°C (>67%) or lower. These pathways explore the energy, land-use, and climate system interactions and thus help identify required energy sector transformations to reach specific long-term climate targets. However, reporting of investment needs outside the energy sector was scarce, reducing the explanatory power of the shown total investment need in the context of overall investment needs (Ekholm et al. 2013; IPCC 2018, Box 4.8; McCollum et al. 2018; Bertram et al. 2021). The modelling of these scenarios is done with a variation of scenario assumptions along different dimensions (*inter alia* policy, socio-economic development and technology availability), as well as with different modelling tools which represent different assumptions

about the structural functioning of the energy-economy-land-use system (see Annex III: 'Scenarios and modelling methods' for details). Tables 15.2 and 15.3 focus on the near-term (2023–2032) investment requirements in the energy sector and how these differ depending on temperature category. Figures 3.36 and 3.37 present the data for the medium term (2023–2052). The results highlight both requirements for increased investments and a shift from fossil towards renewable technologies and efficiency for more ambitious temperature categories. The substantial ranges within each category reflect multiple pathways, differentiated by socio-economic assumptions, technology, and so on. It is necessary to open up these extra dimensions and contrast them with national and sub-regional analysis to understand how investment requirements depend on particular circumstances and assumptions within a country for a specific technology. Limiting peak temperature to levels of 1.5°C–2°C requires rapid decarbonisation of the global energy systems, with the fastest relative emission reductions occurring in the power generation sector (Hirth and Steckel 2016; Luderer et al. 2018).

This requires fast shifts of investment as infrastructures in the power sector generally have long lifetimes of a few decades. In global modelled pathways that limit warming to 1.5°C (>50%) with no or limited overshoot, investments into non-biomass renewables (especially solar and wind, but also including hydro, geothermal, and others not shown in Table 15.2) increase to over USD1 trillion yr⁻¹ in 2030, increasing by more than factor 3 over the values of around USD250–300 billion yr⁻¹ that have been relatively stable over the last decade (IEA 2019a). Overall, electricity generation investments increase considerably, reflecting the higher relevance of capital expenditures in decarbonised electricity systems. While decreasing technology costs have substantially reduced the challenge of high capital intensity, still remaining relative disadvantages in terms of capital intensity of low-carbon power technologies can especially create obstacles for fast decarbonisation in countries with high interest rates, which decrease the competitiveness of those technologies (Iyer et al. 2015; Hirth and Steckel 2016; Steckel and Jakob 2018; Schmidt et al. 2019). CCS as well as nuclear will not drive investment needs until 2030, given considerably longer lead-times for these technologies, and the lack of a significant project pipeline currently.

Table 15.2 | Global average yearly investments from 2023–2032 for electricity supply in billion USD₂₀₁₅.

Category	Fossil	Nuclear	Storage	Transmission and distribution	Non-Biomass Renewables		
					All	Thereof

Note: Global average yearly investments from 2023–2032 (in USD₂₀₁₅). Electricity subcomponents are not exhaustive. Hydro, geothermal, biomass and others are not shown, as these are shown to be of smaller magnitude (Chapter 3). Difference between non-biomass renewables and solar/wind represents hydro and in some scenarios geothermal, tidal, and ocean. Scenarios are grouped into common AR6 categories (vertical axis, C1–C3). The numbers represent medians across all scenarios within one category, and rounded brackets indicate inter-quartile ranges, while the numbers in squared brackets indicate number of scenarios. C6, C7, and C8 are not shown in Table 15.2. Reference C5 category for Transmission and Distribution (T&D) is 364bn (294bn to 445bn) [111] used for calculation of incremental needs in Figure 15.4. Data source: AR6 Scenarios Database.

Note: Average yearly investments from 2023–2032 for electricity generation capacity, by aggregate regions (in billion USD₂₀₁₅). Further notes see Table 15.2. Reference C5 category for Transmission and Distribution shown in Table 15.2 as it is used for calculation of incremental needs for Figure 15.4. Vertical axis, C4–C8 except Transmission and Distribution not shown. Data source: AR6 Scenarios Database.

What is apparent is that the bulk of investment requirements corresponds to medium- and low-income countries in Asia, Latin America, the Middle East and Africa, as these still have growing energy demand, and it is still considerably lower than the global average. This illustrates a vital opportunity to ensure the build-up of sustainable energy infrastructures in these regions and constitutes a risk of additional carbon lock-in if investments into fossil

infrastructures, especially coal-fired power plants, and uncontrolled urban expansion, continue.

Investment needs in electrification derived from IAMs do not include systematically investments in end-use equipment and distribution (Box 4.8 in SR1.5 (IPCC 2018)). Model-based estimates of investment needs don't have the regional granularity to single out

LDCs, as model regions typically are defined based on geographic proximity and therefore aggregate LDCs and other countries. With the average electricity consumption per capita in Africa increasing to 0.68–0.87 (1.43–2.92) MWh in 2030 (2050) yr^{-1} and remaining at the very low end of the global range [0.46 in Africa compared to the upper end of 12.02 in North America, MWh per capita and year in 2020], the targeted full electrification until 2030 appears unrealistic across all scenarios. SEforAll and IEA estimate assumed investment needs to decentralised end-user electrification to come in around USD40 billion on average until 2030 (SEforAll and CPI 2020; IEA 2021d).

Quantitative analysis of investment needs in energy generation based on IRENA and IEA data and comparison to AR6 scenario database output.

According to IRENA, the government plans in place today call for investing at least USD95 trillion in energy systems over the coming three decades (2016–2050) (IRENA 2020c). Redirecting and increasing investments to ensure a climate-safe future (Transforming Energy Scenario, TES) would require reaching on average around 1 trillion $\text{USD}_{2015} \text{ yr}^{-1}$ (average until 2030) for electricity generation as well as grids and storage, increasing to above 2 trillion $\text{USD}_{2015} \text{ yr}^{-1}$ (average until 2030) in the 1.5 scenario (IRENA 2021). IEA's respective SDS and NZE scenarios come in at average annual investments between USD1.0 trillion yr^{-1} and USD1.6 trillion yr^{-1} (average until 2030) (IEA 2021b). These additional data points for the C1 and C3 category underpin the range presented in the AR6 Scenarios Database for needs until 2032 despite the slightly varying periods.

In contrast to the IAMs, IRENA and IEA assessments do not allow for an analysis of mitigation-driven investment needs in transmission and distribution, which likely results in an overestimation of the mitigation-driven investment needs in their analysis.

It is worth highlighting that driven by technology cost assumptions, IRENA forecasts falling average annual investments needs for energy, but also energy efficiency, for the period 2030–2050 compared to 2020–2030. In the 1.5°C scenario (1.5-S) the total annual investment needs excluding fossils and nuclear decrease from 5.0 trillion USD_{2015} until 2030 yr^{-1} to 3.8 trillion $\text{USD}_{2015} \text{ yr}^{-1}$ for 2030–2050 (IRENA 2021). In IAM scenarios of Category C1, electricity supply investments (including generation, transmission and distribution, and storage) remain flat at 2.2 trillion $\text{USD}_{2015} \text{ yr}^{-1}$ through the coming three decades in absolute terms. Given rising GDP, the complementary methods and sources thus consistently point to a peak in electricity supply investments as a percentage of GDP in mitigation scenarios in the coming decade. This reflects the fact that the coming decade requires low-carbon power generation investments to both cover the demand increase and (partly premature) replacement of fossil generation capacities, both concentrated in emerging and developing countries. Relative investment numbers for electricity measured against GDP then decrease towards 2050, as they only need to cover natural replacement and increasing demands (which due to electrification will also pick up in developed countries), and due to further declining technology costs. Investments for low-carbon fuel

supply like hydrogen and synthetic fuels, and for direct electrification equipment (heat pumps, electric vehicles (EV), etc.) scale up from much lower levels and will likely continue to grow as a share of GDP until mid-century, though uncertainties and accounting is still much more uncertain. (Bertram et al. 2021).

Quantitative analysis of investment needs in other sectors.

As described above, investment needs in non-energy sectors tend to be ignored in many integrated assessment models with studies for individual countries or regions providing a more fragmented picture only. However, the quality of estimates is likely not to be less robust given the drawbacks of integrated assessment models.

Chapter 7 stresses the importance of opportunity costs for AFOLU mitigation options, in particular for afforestation and avoided deforestation projects, and derives net annual costs of around USD278 billion yr^{-1} in the next several decades, mostly opportunity costs. Net costs of delivering 5–6 Gt $\text{CO}_2 \text{ yr}^{-1}$ of forest related carbon sequestration and emission reduction around 2050 as assessed with sectoral models are estimated to reach to ~ USD400 billion yr^{-1} by 2050, excluding externality costs (Chapter 7.4).

Energy efficiency. Estimates on energy investment needs vary significantly with a low level of transparency with regard to underlying technology cost assumptions burdening the confidence levels.

IRENA only selectively reports financing needs for energy efficiency in buildings and industry as separate categories. For the 1.5-S average yr^{-1} needs until 2050 come in at 963 billion USD_{2015} for buildings, 102 billion USD_{2015} for heat pumps, and 354 billion USD_{2015} for industry. Applying the relative share of these categories on higher total needs until 2030, around 1.8 trillion $\text{USD}_{2015} \text{ yr}^{-1}$ in buildings and industry are needed in the 1.5-S. For the TES cumulative energy efficiency investment needs until 2030 are stated at 29 trillion USD_{2015} translating into an yearly average of around 1.7 trillion $\text{USD}_{2015} \text{ yr}^{-1}$, excluding transportation. IEA estimates come in at a much lower level at 0.6 and 0.8 billion $\text{USD}_{2015} \text{ yr}^{-1}$ on average between 2026–2030 for their SDS and NZE scenarios.

Transportation. For the transportation sector, OECD has presented the most comprehensive assessment of financing needs in the AR6 database based on IEA data with the annual average coming in at USD2.7 trillion between 2015 and 2035 in modelled global pathways that limit warming to 2°C (>67%). The assessment comprises road, rail and airports/ports infrastructure, with only rail infrastructure being considered in this analysis.

On a regional level, Oxford Economics (2017) shows that annual infrastructure investments between 2016 and 2040 vary widely. For all available countries ($n=50$) estimates count close to 0.4 trillion $\text{USD}_{2015} \text{ yr}^{-1}$, including 0.217 trillion $\text{USD}_{2015} \text{ yr}^{-1}$ for China. Based on available data for nine African countries, investments in rail infrastructure range from USD0.1 billion in Senegal to USD1.6 billion in Nigeria. Osama et al. (2021) highlight a USD4.7 billion financing gap for African countries in the transport sector. In Latin America Oxford Economics (2017) identifies Brazil as frontrunner of required rail investments with USD8.3 billion, followed by Peru with USD2.3 billion.

In total, developed countries' financing needs mount up to almost USD120 billion yr^{-1} ($n=15$, mean=7.97bn USD) for rail infrastructure. Financing needs in developing countries (excluding LDCs and excluding China) mount up to almost USD50 billion yr^{-1} ($n=27$, mean=1.78bn USD, excluding China). Oxford Economics (2017) reports rail infrastructure financing needs for China of more than USD200 billion yr^{-1} between 2016 and 2040.

Fisch-Romito and Guivarch (2019) show, by endogenising the impact of urban infrastructure policies on mobility needs and modal choices that transportation investment needs globally might be lower in low-carbon pathways compared with baselines, with lower investments in road and air infrastructure. This does mean that higher investments are not needed over the following two decades; this is confirmed by Rozenberg and Fay (2019) that strong policy integration between urban, transportation and energy policies reduce the total investment gap.

IRENA as well as IEA have presented estimates for energy efficiency investments in the transport sector. For the 1.5-S scenario, IRENA indicates average investment needs of USD₂₀₁₅ 0.2 trillion yr^{-1} for EV infrastructure, USD₂₀₁₅ 0.2 trillion yr^{-1} for transport energy efficiency and USD₂₀₁₅ 0.3 trillion yr^{-1} for EV batteries (average until 2030) (IRENA 2020d). IEA indicates a total of around 0.6 and 0.7 trillion USD₂₀₁₅ yr^{-1} for transport energy efficiency in the SDS and IEA scenarios for the 2026–2030 period (IEA 2021c). Many investment categories relating to mitigation options, in particular with regard to behavioural change and transport mode changes (Chapter 10, Figure SPM.8), are neglected in these analyses despite their significant mitigation potential.

AFOLU. The Food and Land Use Coalition estimates additional investment needs for ten critical transitions for the global food and land use systems to achieve the long-term global goal (LTGG) and SDGs. Additional annual investment needs until 2030 add up to USD300–350 billion. Considering the change in global diets as well as the land-based nature-based solutions only, annual investment needs would come in between USD110–135 billion.

Chapter 7 stresses the importance of opportunity costs for AFOLU mitigation options, in particular for afforestation projects, and derives average yearly investment needs of around 278 billion USD₂₀₁₅ yr^{-1} until 2030 rising to 431 billion USD₂₀₁₅ yr^{-1} over the next several decades, including opportunity costs. The estimate is based on an assumption of emission reductions consistent with pathways C1–C4, leading to average abatement of 9.1 GtCO₂ yr^{-1} (median range 6.7–12.3 GtCO₂ yr^{-1}) from 2020–2050 and marginal costs of USD100 per tonne CO₂, excluding investments in bioenergy with carbon capture and storage and changes in food consumption and food waste (Section 7.4). The largest investments are projected to occur in Latin America, South-East Asia, and Africa, constituting 61% of total expenditure. The implied change of land use might trigger negative effects on other SDGs which need to be addressed to offer robust safeguards and labelling for investors.

However, given the strong interlinkage of the presented transitions and accumulated effects, climate change related investments can hardly be separated (The Food and Land Use Coalition 2019). Shakhovskoy et al. (2019) present an overview of financing needs of small-scale farmers globally, however, without focusing on the required climate-related investments. According to their assessment, 270 million smallholder farmers in South and South-East Asia, sub-Saharan Africa and Latin America face approximately USD240 billion of financing needs, thereof USD100 billion short-term agricultural needs, USD88 billion long-term agricultural needs and USD50 billion non-agricultural needs (Shakhovskoy et al. 2019). These numbers can only provide 'an indication of the magnitude of the climate investments required in small-scale agriculture' (CPI 2020). Table 15.4 summarises the studies used as well as adjustments made to determine needs for the gap discussion in Section 15.5.2.

Adaptation financing needs. Financing needs for adaptation are even more difficult to define than those of mitigation because mobilising specific adaptation investments is only part of the challenge since ultimately improving societies' adaptive capacities depends on

Table 15.4 | Sector studies to determine average financing needs.

Sector	Studies	Global ranges trillion USD yr^{-1} – Confidence Level		Regional breakdown		Comment
Energy	IAM database, SEforAll (SEforALL and CPI 2020), IRENA 1.5-S and TES scenarios (IRENA 2021), IEA SDS and NZE scenarios (IEA 2021b)	0.8–1.5	High confidence	Detailed breakdown for R10 possible for IAM database and applied to the derived range	Medium confidence	Wide ranges primarily driven by varying assumptions with regard to grid investments relating to the increased renewable energy penetration.
Energy Efficiency	IRENA 1.5-S and TES scenarios, IEA SDS and NZE scenarios	0.5–1.7	Medium confidence	Adjustments required to regional categorisation by IEA and IRENA	Low-medium confidence	Medium confidence levels due to missing transparency with regard to underlying assumptions on technology costs. Low-to-medium confidence level on regional allocations due to required adjustments.
Transport	OECD/IEA (OECD 2017b) and Oxford Economics (2017) on rail investment data, IRENA 1.5-S and TES scenarios, IEA SDS and NZE scenarios for transport (energy efficiency) and electrification	1.0–1.1	Medium confidence	Adjustments required to regional categorisation by IEA and IRENA	Low-medium confidence	Needs including battery costs, not total costs, of electric vehicles, likely underestimation of needs due to missing data points on rail infrastructure.
AFOLU	Chapter 7 analysis, Section 7.4; The Food and Land Use Coalition (Land use Coalition (2019); (Shakhovskoy et al. 2019)	0.1–0.3	High confidence	Breakdown for R10 possible for Chapter 7 analysis	Medium confidence	Upper end of range includes opportunity costs as these likely increase costs of investment in land.

Note: Total range USD2.3 trillion to USD4.5 trillion yr^{-1} .

the SDGs' fulfilment (Hallegatte et al. 2016). Bridging the investment gap on irrigation, water supply, health care, energy access, and quality buildings is an essential enabling condition for adapting to climate change. The scenario analysis conducted by Rozenberg and Fay (2019) show that fulfilling the SDGs to improve the adaptive capacity of low- and middle-income countries would require investments in water supply, sanitation, irrigation and flood protection that would account for about 0.5% of developing countries' GDP in a baseline scenario to 1.85% and 1% with a strong and anticipatory policy integration (USD664 billion and 351 billion on average by 2030).

Most studies choose to assess public sector projects, ignoring household-level investments as well as private sector adaptation (UNEP 2018; Buchner et al. 2019). UNEP's 2020 Adaptation Gap Report estimates adaptation costs amounting to 140–300 billion USD yr⁻¹ in 2030 and USD280–500 billion yr⁻¹ in 2050 (UNEP 2021). Over 100 countries included adaptation components in their intended NDCs (INDCs) and approximately 25% of these referenced national adaptation plans (NAPs) (GIZ 2017a) but estimates of the financing required for NAP processes is not available. These NAPs, as formally agreed under the UNFCCC in 2010, are iterative, continuous processes that have multiple stages with a developmental phase that requires country-specific financing of primarily which comprises grants, bond issuance or debt conversion (NDC Partnership 2020, NAP Global Network 2017). At the same time, multilateral climate funds such as the Green Climate Fund and the GEF/Least Developed Countries Fund offer 'readiness and preparatory support' and implementation for the NAPs and adaptation planning process (GCF 2020a; GEF 2021a,b). There has been no significant updating of adaptation cost estimates since UNEP's (UNEP 2016, 2018). The Global Commission on Adaptation makes the case that investing USD1.8 trillion in early warning system, climate-resilient infrastructure, global mangrove and resilient water resources would generate about USD1.7 trillion in benefits due to avoided cost and non-monetary and social resources (Verkooijen 2019; UNEP 2021).

There is increasing recognition of rising adaptation challenges and associated costs within and across developed countries. Undoubtedly many developed countries are spending more on a wide range of adaptation issues, both as preventive measures and building resilience (greening infrastructure, climate-proofing major projects and managing climate-related risks) against the impacts of climate change extreme weather events (US GCRP 2018a). Developed countries' climate change adaptation spending covers areas such as federal insurance programmes, federal, state and local property and infrastructure, supply chains, and water systems.

15.5 Considerations on Financing Gaps and Drivers

15.5.1 Definitions

The analysis of financing gaps in climate action, which is used to measure implementation action and mitigation impact (FS-UNEP Centre and BNEF 2019) cannot be carried out as a pure demand-side challenge, in isolation from the analysis of barriers to deploy funds (e.g., Ramlee and Berma 2013) and to take investment

initiatives. These barriers are 'friction that prevents socially optimal investments from being commercially attractive' (Druce et al. 2016). They are at the root of the 'microeconomic paradox' of a deficit of infrastructure investments despite a real return between 4% and 8% (Bhattacharya et al. 2016), of the low share of carbon-saving potentials tapped by dedicated policies such as energy renovation programmes (Ürge-Vorsatz et al. 2018), and, more generally of a demand for climate finance lower than the volume of economically viable projects (de Gouvello and Zelenko 2010; Timilsina et al. 2010).

A few exercises tried assess the consequences of the perpetuation of these drivers on the magnitude of the financing gap. They suggest, comparing the evolution of the infrastructure investment trends (beyond energy) by comparison with what they should be in an optimal scenario, a cumulative deficit between 19% (Oxford Economics 2017) and 32% (Arezki et al. 2016). The volume of this gap is of the same order of magnitude as the incremental infrastructure investments (energy and beyond) for meeting a 1.5°C target (2.4% of the world GDP on average) (Box 4.8 of SR1.5 (IPCC 2018)) calculated by exercises assuming no pre-existing investment gap. This figure is consistent with the 1.5% to 1.8% assessed by the European Commission (2020) for Europe and the 2% of the IMF (2021d) for the G20, which do not encompass many developing countries for which economic take-off is today fossil fuels dependent. For low- and middle-income economies, Rozenberg and Fay's (2019) results suggest to increase the infrastructure investments by 2.5 to 6 percentage points of GDP to cover both the reduction of the structural investment gap and the specific additional costs for bridging it with low-carbon and climate-resilient options. These assessments indicate the challenge at stake but do not exist at very disaggregated sectoral and regional levels for sectors other than energy.

The below quantitative analysis does not differentiate between financing gaps driven by barriers within or outside the financial sector given that the IAM models as well as most other studies used do not incorporate actual risk ranges depending on policy strength and coherence and institutional capacity, low-carbon policy risks, lack of long-term capital, cross-border currency fluctuation, and pre-investment costs and barriers within the financial sector that discourage private sector financing. They comprise short-termism (UNEP Inquiry 2016b), high perceived risks for mitigation-relevant technologies and/or regions (information gap through incomplete/asymmetric information, (Kempa and Moslener 2017; Clark et al. 2018)), lack of carbon pricing effects (Best and Burke 2018), home bias (results in limited balancing for regional mismatches between current capital and needs distribution, (Boissinot et al. 2016)), and perceived high opportunity and transaction costs (results from limited visibility of future pipelines and policy interventions; SME financing tickets and the missing middle, (Grubler et al. 2016)). In addition, barriers outside the financial sector will have to be addressed to close future financing gaps. The mix and dominance of individual barriers might vary significantly across sectors and regions and is analysed below.

The interpretation of the quantitative analysis thus needs to be performed, taking into account the qualitative needs assessment in Section 15.4.1 and the evolution of parameters that determine the risk-weighted relative attractiveness of low-carbon and climate-resilient investments compared to other investment opportunities. With some

institutions having announced climate finance commitments and/or targets (see also Box 15.4), the actual asset allocation of commercial financial sector players including sectoral and regional focus will respond to tangible and financially viable investment opportunities available in the short term. Robust long-term pathways to create such conditions for a significant private sector involvement rarely exist and expectations on private sector involvement in some critical sectors/regions might be too high (Clark et al. 2018).

15.5.2 Identified Financing Gaps for Sector and Regions

The following section compares recent climate finance flows as reported by CPI and IEA to needs derived in Section 15.4, ignoring the slight mismatch in time horizons. The analysis ignores interlinked gaps, in particular infrastructure investment gaps and other SDG-related investment gaps, which need to be addressed in parallel to reach the LTGG but also at least partially to facilitate green investments.

Figure 15.4 | Breakdown of recent average (downstream) mitigation investments and model-based investment requirements for 2020–2030 (USD billion) in scenarios that likely limit warming to 2°C or lower. Mitigation investment flows and model-based investment requirements by sector / segment (energy efficiency in buildings and industry, transport including electricity generation, transmission and distribution including electrification, and agriculture, forestry and other land use), by type of economy, and by region (see Annex II Part I Section 1: By region is based on intermediate level (R10) classification scheme. By type of economy is based on intermediate level (R10) classification scheme, which considers 'North America', 'Europe', and 'Australia, Japan and New Zealand' as developed countries, and the other seven regions as developing countries). Breakdown by sector / segment may differ slightly from sectoral analysis in other contexts due to the availability of investment needs data. The granularity of the models assessed in Chapter 3, and other studies, do not allow for a robust assessment of the specific investment needs of LDCs or SIDSs. Investment requirements in developing countries might be underestimated due to missing data points as well as underestimated technology costs. In modelled pathways, regional investments are projected to occur when and where they are cost-effective to limit global warming. The model quantifications help to identify high-priority areas for cost-effective investments, but do not provide any indication on who would finance the regional investments. Investment requirements and flows covering downstream / mitigation technology deployment only. Data includes investments with a direct mitigation effect, and in the case of electricity, additional transmission and distribution investments. See section 15.4.2 Quantitative assessment of financing needs for detailed data on investment requirements. Data on mitigation investment flows are based on a single series of reports (Climate Policy Initiative, CPI) which assembles data from multiple sources. Investment flows for energy efficiency are adjusted based on data from the International Energy Agency (IEA). Data on mitigation investments do not include technical assistance (i.e., policy and national budget support or capacity building), other non-technology deployment financing. Adaptation only flows are also excluded. Data on mitigation investment requirements for electricity are based on emission pathways C1, C2 and C3 (Table SPM.1). For electricity investment requirements, the upper end refers to the mean of C1 pathways and the lower end to the mean of C3 pathways. Data points for energy efficiency, transport and AFOLU cannot always be linked to C1–C3 scenarios. Data do not include needs for adaptation or general infrastructure investment or investment related to meeting the SDGs other than mitigation, which may be at least partially required to facilitate mitigation. The multiplication factors show the ratio of average annual model-based mitigation investment requirements (2020–2030) and most recent annual mitigation investments (averaged for 2017–2020). The lower and upper multiplication factors refer to the lower and upper ends of the range of investment needs.

Given the multiple sources and lack of harmonised methodologies, the data can only be indicative of the size and pattern of investment gaps. The gap between most recent flows and required investments is only a single indicator. A more comprehensive (and qualitative) assessment is required in order to understand the magnitude of the challenge of scaling up investment in sectors and regions. The analysis also does not consider the effects of misaligned flows. (15.3, 15.4, 15.5, Table 15.2, Table 15.3, Table 15.4)

Total investments in mitigation need to increase by around three and six times with significant gaps existing across sectors and regions⁸ (*high confidence*). The findings on still significant gaps and limited progress over the past few years to some extent seem to contradict the massive increase in commitments by financial institutions. As discussed in Section 15.6, the investment gap is not due to global scarcity of funds.

However, these investment gaps have little explanatory power in terms of the magnitude of the challenge to mobilise funding. In addition to measurement challenges from different definitions and data gaps, sectors and regions offer highly divergent financial risk-return profiles, in particular due to missing or weak regulatory environments consistent with ambitions levels, and economic costs as well as limited local capital markets, limited institutional capacity to ensure safeguard, standardisation, scalability and replicability of investment opportunities and financing models, and a pipeline ready for commercial investments. Moreover, soft costs and institutional capacity for enabling environment that can be prerequisite for addressing financing gaps are ignored when focusing on investment cost needs.

Sectoral considerations. The renewable energy sector attracted the highest level of financing in absolute and relative terms with business models in generation being proven and rapidly falling technology costs driving the competitiveness of solar photovoltaic and onshore wind, even without taking account of the mitigation component (FS-UNEP Centre and BNEF 2019; IRENA 2020a). This investment activity comes in line with the first generation of NDCs and their heavy focus on mitigation opportunities in the renewable energy sector (Pauw et al. 2016; Schletz et al. 2017). Still, the investment gap tends to remain stable with flows over the past years not showing an upward trend.

Comparing annual average total investments in global fuel supply and the power sector of approximately USD1.5 trillion⁹ yr⁻¹ in 2019 (IEA 2020a) to the investment in the Stated Policies Scenario (approximately 1.7 trillion USD₂₀₁₅ yr⁻¹) and the Sustainable Development Scenario (approximately 1.8 trillion USD₂₀₁₅ yr⁻¹) in 2030 underlines the required shift of existing capital investment from fossil to renewables even more than the need to increase sector allocations (Granoff et al. 2016; McCollum et al. 2018).

Ensuring access to the heavily regulated electricity markets is a key driver for an accelerated private sector engagement (IFC 2016; FS-UNEP Centre and BNEF 2018; REN21 2019), with phasing out of support schemes and regulatory uncertainty being a major driver for reduced investment volumes in various regional markets in the past years (FS-UNEP Centre and BNEF 2015, 2016, 2017, 2018, 2020). Strategic investors and corporate investments by utilities dominate the investment activity in developed countries and countries in transition (BNEF 2019) based on the competitiveness of renewable

energy sources. Reasonable auction results based on a substantial private-sector competition for investments have also been achieved in selected developing countries driven by rather standardised contract structures and the increased availability of risk mitigation instruments addressing political and regulatory risks and home bias constraints (FS-UNEP Centre and BNEF 2019; IRENA 2020a). Development finance institution (DFI) climate portfolios tend to be driven by concessional loans for renewable energy generation assets with equity often being provided by (semi-) commercial investors (Section 15.3) which will have to change to accelerate renewable energy investment activity.

Given the wide range of estimates on current investment flows into energy efficiency, substantial uncertainty exists with regard to the magnitude of the investment gaps. While CPI publishes investment levels of 41 billion USD₂₀₁₅ in 2019 and 24 billion USD₂₀₁₅ in 2020 for energy efficiency, counting majorly international flows, IEA results come in at a much higher level of around 250 billion USD₂₀₁₅ annually between 2017 and 2020 (IEA 2021c) and IRENA (2020c) estimates energy efficiency investments in buildings between 2017–2019 at an average of USD139 billion yr⁻¹.

Public sector investments in the transport sector have increased significantly in the past years reflecting the increased interest of capital markets in renewable energy and the efficient and corresponding reallocation of public funding. Provision of funding by capital markets for public transport infrastructure among others heavily depends on suitable financing vehicles and increased funding for development of projects with a low level of standardisation (OECD 2015a).

Both IRENA and IEA include only incremental costs of EVs in their estimates on needs while CPI, when measuring actual flows, includes those at full costs. Total private flows for EVs included in CPI numbers amount to USD41 billion in 2018 (Buchner et al. 2019), representing more than 80% of private sector finance into the transport sector, around one third of total public and private funding to the transport sector in 2018. This likely results in an underestimation of the financing gap – in addition to the fact that estimates for investment needs for rail infrastructure are only available for selected countries.

Current financing of land-based mitigation options is less than USD1 billion yr⁻¹ representing only 2.5% of climate mitigation funding, significantly below the potential proportional contribution (Buchner et al. 2019). A stronger focus on deforestation-free value chain, including a stronger reflection in taxonomies and financial sector investment decision processes are necessary to *ensure* an alignment of financial flows with the LTGG. Taking into account the specifics of land-based mitigation (in particular long investment horizons, strong dependency on the monetisation of mitigation effects, strong public sector involvement) a significant scale-up of commercial financing to the sector can hardly be expected in the absence of strong climate

⁸ In modelled pathways, regional investments are projected to occur when and where they are most cost-effective to limit global warming. The model quantifications help to identify high-priority areas for cost-effective investments, but do not provide any indication on who would finance the regional investments.

⁹ In the chapter, USD units are used as reported in the original sources in general. Some monetary quantities have been adjusted selectively for achieving comparability by deflating the values to constant US Dollar 2015. In such cases, the unit is explicitly expressed as USD₂₀₁₅.

policies (Clark et al. 2018). Agriculture is likely to develop more potential to mobilise private finance than the forest sector given its strong linkage to food security and hunger and shorter payback periods. The significant gap in land-based mitigation finance also indicates the crucial lack of finance to the bottom of the pyramid.

Agricultural support is an important source of distortions to agricultural incentives in both rich and poor countries (Mamun et al. 2019) ranging from the largest component of the support, market price supports, increased gross revenue to farmers as a result of higher prices due to market barriers created by government policies, to production payments and other support including input subsidy (e.g., fertiliser subsidy) (Searchinger et al. 2020). USD600 billion of annual governmental support for agriculture in the OECD database contributes only modestly to the related objectives of boosting crop yields and just transition (Searchinger et al. 2020). A review of NDCs of 40 developing countries which submitted a NDC to the UNFCCC Interim NDC Registry by April 2017, and include within their NDC efforts to REDD+ via support from the UN-REDD Programme and/or World Bank Forest Carbon Partnership Facility, indicates that none of the countries reviewed mention fiscal policy reform of existing finance flows to agricultural commodity production or other publicly supported programmes that affect the direct and underlying drivers of land use conversion (Kissinger et al. 2019).

Analysis by region and type of economy. The analysis of gaps by type of economy illustrates the challenge for developing countries. Estimated mitigation financing needs as a percentage of mean 2017–2020 GDP in USD₂₀₁₅ comes in at around 2–4% for developed countries, and around 4–9% for developing countries (*high confidence*) (Figure 15.4). Climate finance flows have to increase by a factor of four to seven in developing countries and three to five in developed countries. This disparity is further exacerbated when considering adaptation, infrastructure and SDG-related investment needs (*high confidence*) (Hourcade et al. 2021a). However, differences across developing countries are significant. Flows to Eastern Asia, with its annual average flows (2017–2020) of 252 billion USD₂₀₁₅ being dominated by China (more than 95% of total mitigation flows to Eastern Asia), would have to increase by a factor of two to four, a comparable level to developed countries. Section 15.6.2 elaborates on outlooks with regard to fiscal space and ability to tap capital markets, in particular for developing countries. In particular, attention must accelerate on low-income Africa. This large continent currently contributes very little to global emissions, but its rapidly rising energy demands and renewable energy potential versus its growing reliance on fossil fuels and ‘cheap’ biomass (especially fuelwood for cooking and charcoal, with impacts on deforestation) amid fast-rising urbanisation makes it imperative that institutional investors and policymakers recognise the very large ‘leap-frog’ potential for the renewable energy transition as well as risks of lock-in effects in infrastructure more generally in Africa that is critical to hold the global temperatures rise to well below 2°C in the longer term (2020–2050). Overlooking this transition opportunity, rivalling China, India, USA and Europe, would be costly. Policies centred around the accelerated development of local capital markets for energy transitions – with support from external grants, supranational guarantees and recognition of carbon remediation assets –

are crucial options here, as in other low-income countries and regional settings. Notably, climate finance flows to African countries might have even decreased for mitigation technology deployment (stagnated for adaptation between 2017 and 2020), widening the finance gap in African countries in the recent years (*high confidence*).

Over 80% of climate finance is reported to originate and stay within borders, and even higher for private climate flows (over 90%) (Boissinot et al. 2016). There are multiple reasons for such ‘home bias’ in finance – national policy support, differences in regulatory standards, exchange rate, political and governance risks, as well as information market failures. The extensive home bias means that even if national actions are announced and intended to be implemented unilaterally and voluntarily, the ability to implement them requires access to climate finance which is constrained by the relative ability of financial and capital markets at home to provide such financing, and access to global capital markets that requires supporting institutional policies in source countries. ‘Enabling’ public policies and actions locally (cities, states, countries and regions), to reduce investment risks and boost domestic climate capital markets financing, and to enlarge the pool of external climate financing sources with policy support from source capital countries thus matters at a general level. The biggest challenge in climate finance is likely to be in developing countries, even in the presence of enabling policies and quite apart from any other considerations such as equity and climate justice (Klinsky et al. 2017) or questions about the equitable allocations of future ‘climate budgets’ (Gignac and Matthews 2015). The differentiation between developed and developing countries matters most on financing. Most developed countries have already achieved very high levels of incomes, have the largest pool of capital stock and financial capital (which can be more easily redeployed within these countries given the home bias of financial markets), the most well-developed financial markets and the highest sovereign credit ratings, in addition to starting with very high levels of per capita carbon consumption – factors that should allow the fastest adjustment to low-carbon investments and transition in these countries from domestic policies alone. The financial and economic circumstances are more challenging in many developing countries, even within a heterogeneity of circumstances across countries. The dilemma, however, is that the fastest rates of the expected increase in future carbon emissions are in developing countries. The biggest challenge of climate finance globally is thus likely to be the constraints to climate financing because of the opportunity costs and relative under-development of capital markets and financing constraints (and costs) at home in developing countries, and the relative availability or absence of adequate financing policy support internationally from developed countries. The Paris Agreement and commitment by developed countries to support the climate financing needs of developing countries thus continue to matter a great deal.

Soft costs/institutional capacity (Osama et al. 2021). Most funding needs assessments focus on technology costs and ignore the cascade of financing needs as outlined above. International grant funding or national budget allocations for soft costs like the creation of a regulatory environment can be a prerequisite for the supply of commercial financing for the deployment of technologies. Such critical funding needs might represent a small

share of overall investment needs but current (relatively small) gaps in funding of policy reforms can hinder or delay deployment of large volumes of funding in later years. The role, as well as the approximate volumes of such required timely international grant funding or national budget allocations, appear underestimated in research. The numbers available for the creation of an enabling environment for medium-sized renewable energy (RE) projects in Uganda (GET FIT Uganda 2018) are illustrative only and cannot be transferred as assumptions to other countries without taking into account potentially varying starting points in terms of institutional readiness, pipelines, as well as the general business environment. GET FIT Uganda supported 170 MWp of medium-scale RE capacity triggering investments of USD453 million (GET FIT Uganda 2018), international results-based incremental cost support amounted to USD92 million and project preparation, technical assistance, and implementation support, required USD8 million, excluding support from national agencies.

There is strong evidence of the correlation between institutional capacity of countries and international climate finance flows towards those economies (Adenle et al. 2017; Stender et al. 2019) and a strong need for robust institutional capacity to manage the transformation in a sustainable and human rights based way (Duyck et al. 2018). One example to consider unaddressed social concerns is the ongoing call for feedback by the European Commission and its platform on sustainable finance. It argues for a social taxonomy, that can support the identification of financing opportunities for economic activities contributing to social objectives (European Commission 2021b). SEforAll has highlighted the issue of investments not going to the countries with the greatest need, also partly driven by institutional capacity levels (SEforALL and CPI 2020). Also, most of the developing countries' NDCs are conditional upon international support for capacity building (Pauw et al. 2020). The Climate Technology Centre and Network (CTCN) was created as an operational arm of the UNFCCC Technology Mechanism with the mandate to respond to requests from developing countries. Initial evaluations of the mechanism underpin its importance and value for developing countries but stress long lead times and predictability of future international public finance to maintain operations as key challenges (UNFCCC 2017; DANIDA 2018). While limited pipelines, limited absorptive capacities as well as restricted institutional capacity of countries are often stated as challenges for an accelerated deployment of finance (Adenle et al. 2017), the question remains on the role of international public climate finance to address this gap and whether a concrete current financing gap exists for patient institutional capacity building. While current short-term, mostly project-related, capacity building often fails to meet needs but alternative, well-structured patient interventions and finance could play an important role (Saldanha 2006; Hope 2011) accepting other barriers than financing playing a role as well. One reason why international public climate finance is not sufficiently directed to such needs might be the complexity in measuring intangible, direct outcomes like improved institutional capacity (Clark et al. 2018).

Early stage/venture capital financing/pilot project financing.

Early-stage companies in impact investment sectors with business solutions can contribute positively to climate impact. Figure SPM.8 highlights the need for new business models facilitating parts of the behavioural change. Also, SE4All has underpinned the need for an expansion of available business models to achieve universal access (SEforALL and CPI 2020). Further research and development needs range from resource efficiency of proven technologies and next generation technologies but also new technologies (Chapter 16). Access to early stage financing remains critical with performance in recent years being weak (Gaddy et al. 2016). This historically weak performance of clean tech start-ups burdens the interest of investors in the sector on the one hand and discourages experienced executive talent (Wang and Yee 2020). Besides that, the concentration of venture capital markets in the USA, Europe and India represents a major challenge (FS-UNEP Centre and BNEF 2019; Statistica 2021). With regard to commercial-scale demonstration projects, IEA estimates a need of USD90 billion of public sector finance before 2030 having around USD25 billion already planned by governments to 2030 (IEA 2021c).

Need for parallel rather than sequential investment decisions.

The needs and gaps assessment does not include upstream investment needs required to facilitate the technology deployment as foreseen in the scenarios presented above. For example, for their transforming energy scenario IRENA estimates the number of EVs to increase from around 8 million units in 2019 to 269 million units in 2030 (IRENA 2020c). This would require investments in battery factories amounting to approximately USD207 billion with further investment requirements in the value chain (IRENA 2020d). This illustrates the extent of parallel investments based on goals rather than concrete regulatory interventions and/or demand and poses a problem of upfront investment risks for each industry in the chain in the absence of certainty of the presence of parallel decisions in the upstream and downstream links in the chain. This is a typical element of the 'valley of the death' of innovation (Scherer et al. 2000; Åhman et al. 2017). It discourages risk-taking and slows down the learning-by-doing processes, economies of scale and increasing returns to adoption needed for lowering the costs of systemic technical change (Kahouli-Brahmi 2009; Weiss et al. 2010). Implications for risk perception, financing costs as well as investment decision-making processes and ultimately for feasibility are rarely considered.

Finance for adaptation and resilience. As explained early, the reduction of the infrastructure gap to increase societies' resilience and the implementation of the NAPs will require more and higher levels of sustained financing. Activities mobilised for adaptation and resilience are often not marketable and their financing will continue coming from the public sector (Murphy and Parry 2020) and, at the international level, from grants-based technical assistance or through budgetary support or basket finance for large projects/programmes or sector-wide approaches or multilateral finance under (Non-) UNFCCC¹⁰ that also anticipate supporting NAP implementation – particularly those involving incremental costs and co-benefits,

¹⁰ Those under the UNFCCC, such as the GCF through its USD3 million per country readiness and preparatory support programme, the Least Developed Countries Fund (LDCF) and the Special Climate Change Fund (SCCF), the Pilot Program for Climate Resilience (PPCR) and the Adaptation for Smallholder Agriculture Programme (ASAP) are focused on supporting the preparatory process of the NAPs. But the Adaptation Fund will support the implementation of concrete projects up to USD10 million per country.

which will include sectoral approaches such as water, energy, infrastructures, and food production. According to the UNFCCC, 'in 2015–2016, 3% of international public adaptation finance flows was supplied by multilateral climate funds, while 84% came from development finance institutions and 13% from other government sources' (UNFCCC 2019c). Comprehensive reporting on adaptation finance by Murphy and Parry (2020) and Buchner et al. (2019) argues that flows of finance for adaptation action in developing countries in 2017 and 2018 were estimated to be approximately USD30 billion; this plus an additional estimated flow of USD12 billion for dual adaptation and mitigation actions totalled USD42 billion, accounting for 7.25% of the total estimated international public and private flows of climate finance (Buchner et al. 2019). They are far below the financing needs given in Section 15.4. To date, the private sector has limited involvement in NAPs and adaptation projects and planning but can be involved through public-private partnership (Section 15.6.2.1) and other incentives provided by governments (Schmidt-Traub and Sachs 2015; Druce et al. 2016; Koh et al. 2016; UNEP 2016; NAP Global Network 2017; Murphy and Parry 2020) and innovative private financing mechanisms such as green and blue bonds. However, adaptation financing is only about 2% of the share of green bond financing raised up to June 2019 (UNFCCC 2019c),¹¹ whereas it is about 10% of sovereign green bonds raised (UNFCCC 2019d). (Tuhkanen 2020), in a detailed review of green bond issuance in the Environmental Finance Data base 2019, found that between March 2010 to April 2019, '5% of all green bonds issued were categorised as adaptation and that 'the private sector accounts for a significant proportion of adaptation-related green bond issuances' (Tuhkanen 2020). However, GIZ (2017b), Nicol et al. (2017, 2018a), and Tuhkanen (2020) highlight that there is scepticism about this stream of finance for adaptation due to the factors that have thus far limited the private sector's involvement in adaptation: lack of resilience-related revenue streams, the small scale of some adaptation projects and the overall 'intangibility' of financing adaptation projects (Larsen et al. 2019).

Financing for resilience is limited, unpredictable, fragmented and focused on few projects or sectors and short term as opposed to programmatic and long term (10–15 years) financing to build resilience (ISDR 2009, 2011; Kellett and Peters 2014; Watson et al. 2015). Market-based mechanisms are available but not equally accessible to all developing countries, particularly SIDS and LDCs, and such mechanisms can undermine debt sustainability (OECD and World Bank 2016). While resilience financing is mainly grant funding, concessional loans are increasing substantially and are key sources of financing for disaster and resilience, particularly for upper-middle-income countries (OECD and World Bank 2016). The combination of these trends can contribute to greater levels of indebtedness among many developing countries, many of which are already at or approaching debt distress.

Social protection systems can be linked with a number of the instruments already considered: reserve funds, insurance and catastrophe bonds, regional risk-sharing facilities, contingent credit, in addition to traditional international aid and disaster response. Hallegatte et al. (2017) recommend combining adaptive social

protection with financial instruments in a consistent policy package, which includes financial instruments to deliver adequate liquidity and contingency plans for the disbursement of funds post disaster. Challenges related to financing residual climate-related losses and damages are particularly high for developing countries. Financing losses and damages from extreme events requires rapid pay-outs; the cost of financing for many developing countries is already quite high; and the expense of risk financing is expected to increase as disasters become more frequent, intense and more costly, not only due to climate change but also due to higher levels of exposure. Addressing both extreme and slow onset climate impacts requires designing adequate financial protection systems for reaching the most vulnerable. Moreover, some fraction of losses and damages, both material and non-material, are not commonly valued in monetary terms (non-economic loss) and hence financing requirements are hard to estimate. These non-market-based residual impacts include loss of cultural identity, sacred places, human health and lives (Ameli et al. 2021a; Paul 2019; Serdeczny 2019).

15.6 Approaches to Accelerate Alignment of Financial Flows with Long-term Global Goals

Near-term actions to shift the financial system over the next decade are critically important and possible with globally coordinated efforts. Taking into account the inertia of the financial system as well as the magnitude of the challenge to align financial flows with the long-term global goals, fast action is required to ensure the readiness of the financial sector as an enabler of the transition (*high confidence*). The following subsections elaborate on key areas which can have a catalytic effect in terms of addressing existing barriers – besides political leadership and interventions discussed in other Chapters of AR6.

Addressing knowledge gaps with regard to climate risk analysis and transparency will be one key driver for more appropriate climate risk assessment and efficient capital allocation (Section 15.6.1), efficient enabling environments to support the reduction of financing costs and reduce dependency on public financing (Section 15.6.2), a revised common understanding of debt sustainability, including that negative implications of deferred climate investments on future GDP, particularly stranded assets and resources to be compensated, can facilitate the stronger access to public climate finance, domestically and internationally (Section 15.6.3), climate risk pooling and insurance approaches are a key element of financing of a just transition (Section 15.6.4), the supply of finance to a widened focus on relevant actors can ensure transformational climate action at all levels (Section 15.6.5), new green asset classes and financial products can attract the attention of capital markets and support the scale up of financing by providing standardised investment opportunities which can be well integrated in existing investment processes (Section 15.6.6), a stronger focus on the development of local capital markets can help mobilise new investor groups and to some extent mitigate home bias effects (Section 15.6.7), new business models

¹¹ According to the climate bonds initiative, total green bond finance raised in 2018 was USD168.5 billion across 44 countries (UNFCCC 2019c).

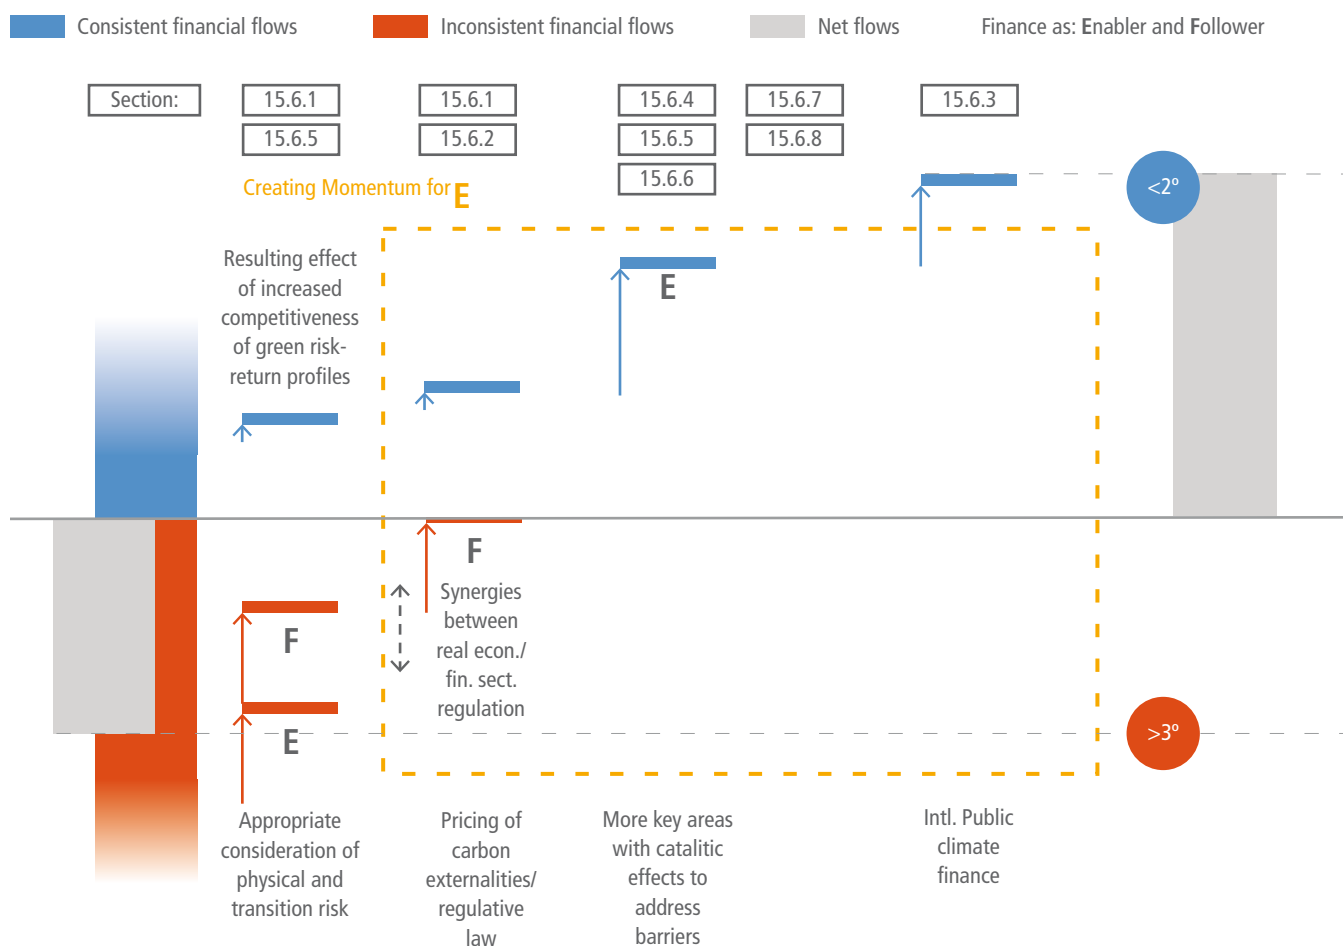

Figure 15.5 | Visual abstract to address financing gaps in Section 15.6.

and financing approaches can help to overcome barriers related to transactions costs by aggregating and/or transferring financing needs and establishing a supply of finance for needs of stakeholder groups lacking financial inclusion (Section 15.6.8).

15.6.1 Addressing Knowledge Gaps with Regard to Climate Risk Analysis and Transparency

Climate change as a source of financial risk.

Achieving climate mitigation and adaptation objectives requires ambitious climate finance flows in the near-term, that is, 5–10 years ahead. However, knowledge gaps in the assessment of climate-related financial risk are a key barrier to such climate finance flows. Therefore, this section discusses the main knowledge gaps that are currently being addressed in the literature and those that remain outstanding.

Climate-related financial risk is meant here as the potential adverse impact of climate change on the value of financial assets. A recent but remarkable development since AR5 is that climate change has been explicitly recognised by financial supervisors as a source of financial risk that matters both for financial institutions and citizens' savings (Bolton et al. 2020). Previously, climate change was mostly

regarded in the finance community only as an ethical issue. The reasons why climate change implies financial risk are not new and are discussed more in detail below. What is new is that climate enters now as a factor in the assessment of financial institutions' risk (e.g., the European Central Bank or the European Banking Authority) and credit rating (Section 15.6.3), and, going forward, into stress-test exercises. This implies changes in incentives of the supervised financial actors, both public and private, and thus changes in the landscape of mitigation action by generating a new potential for climate finance flows. However, critical knowledge gaps remain. In particular, the underestimation of climate-related financial risk by public and private financial actors can explain that the current allocation of capital among financial institutions is often inconsistent with the mitigation objectives (Rempel et al. 2020). Moreover, even a correct assessment of risk, which could provide incentives for divesting from carbon-intensive activities, does not necessarily lead to investing in the technical options needed for deep decarbonisation. Therefore, understanding the dynamics of the low-carbon transition require to fill in at the same time gaps about risk and gaps about investments in enabling activities in a broader sense.

Physical risk. On the one hand, unmitigated climate change implies an increased potential for adverse socio-economic impacts especially in more exposed economic activities and areas (*high confidence*). Accordingly, *physical risk* refers to the component of financial risk

associated with the adverse physical impact of hazards related to climate change (e.g., extreme weather events or sea level rise) on the financial value of assets such as industrial plants or real estate. In turn, these losses can translate into losses on the values of financial assets issued by exposed companies (e.g., equity/bonds) and or sovereign entities as well as losses for insurance companies. The assessment of climate financial physical risks poses challenges in terms of data, methods and scenarios. It requires cross-match scenarios of climate-related hazards at granular geographical scale, with the geolocation and financial value of physical assets. The relationship between the value of physical assets (such as plants or real estate) and the financial value of securities issued by the owners of those assets is not straightforward. Further, the repercussion of climate-related hazards on sovereign risk should also be accounted for.

Transition risks and opportunities. On the other hand, the mitigation of climate change, by means of a transition to a low-carbon economy, requires a transformation of the energy and production system at a pace and scale that implies adverse impacts on a range of economic activities, but also opportunities for some other activities (*high confidence*). If these impacts are factored in by financial markets, they are reflected in the value of financial assets. Thus, *transition risks and opportunities* refers to the component of financial risk (opportunities) associated with negative (positive) adjustments in assets' values resulting directly or indirectly from the low-carbon transition.

The concepts of *carbon stranded assets* (see e.g., Leaton and Sussams 2011), and *orderly vs disorderly transition* (Sussams et al. 2015) which emerged in the NGO community, have provided powerful metaphors to conceptualise transition risks and have evolved into concepts used also by financial supervisors (NGFS 2019) and academics. The term *carbon stranded assets* refers to fossil fuel-related assets (fuel or equipment) that become unproductive. An *orderly transition* is defined here as a situation in which market players are able to fully anticipate the price adjustments that could arise from the transition. In this case, there would still be losses associated with stranded assets, but it would be possible for market players to spread losses over time and plan ahead. In contrast, a *disorderly transition* is defined here as a situation in which a transition to a low-carbon economy on a 2°C path is achieved (i.e., by about 2040), but the impact of climate policies in terms of reallocation of capital into low-carbon activities and the corresponding adjustment in prices of financial assets (e.g., bonds and equity shares) is large, sudden and not fully anticipated by market players and investors. Note the impact could be unanticipated even if the date of the introduction is known in advance by the market players. There are several reasons why such adjustments could occur. One simple argument is that the political economy of the transition is characterised by forces pulling in different directions, including opposing interests within the industry, and mounting pressure from social awareness of unmitigated climate risks. Politics will have to find a synthesis and the outcome could

remain uncertain until it suddenly unravels. Note also that, in order to be relevant for financial risk, the disorderly transition does not need to be a catastrophic scenario in terms of the fabric of markets. It also does not automatically entail systemic risk, as discussed below. Knowledge gaps in this area are related to emerging questions, including: What are, in detail, the transmission channels of physical and transition risk? How to assess the magnitude of the exposure to these risks for financial institutions and ultimately for people's savings? How do transition risk and opportunities depend on the future scenarios of climate change and climate policies? How to deal with the intrinsic uncertainty around the scenarios? To what extent could an underestimation of climate-related financial risk feed back on the alignment of climate finance flows and hamper the low-carbon transition? Should climate risk be explicitly accounted for in regulatory frameworks for financial institutions, such as Basel III for banks and national frameworks for insurance? What lessons from the 2008 financial crisis are relevant here, regarding moral hazard and the trustworthiness of credit risk ratings? The attention of both practitioners and the scientific community to these questions has grown since the Paris Agreement. In the following we review some of the findings from the literature, but the field is relatively young and many of the questions are still open.¹² Damages from climate change are expected to escalate dramatically in Europe (Forzieri et al. 2018) and in some EU countries there is already some evidence that banks, anticipating possible losses on their loan books, lend proportionally less as a consequence.

Assessment of physical risk. There is a literature on estimates of economic losses on physical assets (see Cross-Working Group Box ECONOMIC in chapter 16 of AR6 WGII). Here we discuss some figures and mechanisms that are relevant for the financial system. Significant cost increases have been observed related to increases in frequency and magnitude of extreme events (*high confidence*) (Section 15.4.2). At the global level, the expected 'climate value at risk' (climate VaR) of financial assets has been estimated to be 1.8% along a business-as-usual emissions path (Dietz et al. 2016), with however, a concentration of risk in the tail (e.g., 99th VaR equals to 16.9%, or USD24.2¹³ trillion, in 2016). Climate-related impacts are estimated to increase the frequency of banking crises (up over 200% across scenarios) while rescuing insolvent banks could increase the ratio of public debt to gross domestic product by a factor of two (Lamperti et al. 2019). Further assessments of physical risk for financial assets (Mandel 2020), accounting in particular for the propagation of losses through financial networks, estimate global yearly GDP losses at 7.1% (1.13%) in 2080, without adaptation (with adaptation), the former corresponding to a 10-fold increase with respect to the current yearly losses (0.76% of global GDP). Finally, climate physical risk can impact on the value of sovereign **bonds** (one of the top asset classes by size), in particular for vulnerable countries (Volz et al. 2020).

Insurance pay-outs for catastrophes have increased significantly over the last 10 years, with dramatic cost spikes in years with multiple

¹² In context, while belonging to grey literature, reports from financial supervisors or non-academic stakeholders can be of interest for what they document in terms of changes in perception and incentives among the market players and hence of the dynamics of climate finance flows.

¹³ In the chapter, USD units are used as reported in the original sources in general. Some monetary quantities have been adjusted selectively for achieving comparability by deflating the values to constant USD₂₀₁₅. In such cases, the unit is explicitly expressed as USD₂₀₁₅.

major catastrophes (such as in 2018 with hurricanes Harvey, Irma, and Maria). This trend is expected to continue. The indirect costs of a climate-related flooding event can be up to 50% of the total costs, the majority of which is not covered by insurance (Alnes et al. 2018) (Section 15.6.4). The gap between total damage losses and insurance pay-outs has increased over the past 10 years (Swiss Re Institute 2019). Indeed, the probability of 'extreme but plausible' scenarios will be progressively revised upwards in the 'value at risk'. As a result it becomes more difficult to find financial actors willing to provide insurance, as was observed for real estate in relation to flood and wildfires in California (Ouazad and Kahn 2019). This progressive adjustment would keep the financial system safe (Climate-Related Market Risk Subcommittee 2020; Keenan and Bradt 2020), but transfer to taxpayers the onus of damage compensation and the financing of adaptation investments (OECD 2021c) as well as build up latent liabilities.

Assessment of transition risk. Carbon stranded assets. Fossil fuel reserve and resource estimates exceed in equivalent quantity of CO₂ with virtual certainty the carbon budget available to reach the 1.5°C and 2°C targets (*high confidence*) (Meinshausen et al. 2009; McGlade and Ekins 2015; Millar et al. 2017). In relative terms, stranded assets of fossil fuel companies amount to 82% of global coal reserves, 49% of global gas reserves and 33% of global oil reserves (McGlade and Ekins 2015). This suggests that only less than the whole quantity of fossil fuels currently valued (either currently extracted, waiting for extraction as reserves or assets on company balance sheets) can yield economic return if the carbon budget is respected. The devaluation of fossil fuel assets implies financial losses for both the public sector (Section 15.6.8) and the private sector (Coffin and Grant 2019). Global estimates of potential stranded fossil fuel assets amount to at least 1 trillion, based on ongoing low-carbon technology trends and in the absence of climate policies (cumulated to 2035 with 10% discount rate applied; USD8 trillion without discounting (Mercure et al. 2018a)). With worldwide climate policies to achieve the 2°C target with 75% likelihood, this could increase to over USD4 trillion (until 2035, 10% discount rate; USD12 trillion without discounting). Other estimates indicate USD8–15 trillion (until 2050, 5% discount rate, (Bauer et al. 2015)) and USD185 trillion (cumulated to year 2115 using combined social and private discount rate (Linquiti and Cogswell 2016)). However the geographical distribution of potential stranded fossil fuel assets (also called 'unburnable carbon') is not even across the world due to differences in production costs (McGlade and Ekins 2015). In this context, a delayed deployment of climate finance and consequently limited alignment of investment activity with the Paris Agreement tend to strengthen carbon and thus to increase the magnitude of stranded assets.

Assets directly and indirectly exposed to transition risk.

In terms of types of assets and economic activities, the focus of estimates of carbon stranded assets tends to be on physical reserves of fossil fuel (e.g., oil fields) and sometimes financial assets of fossil fuel companies (van der Ploeg and Rezai 2020). However, a precondition for a broader analysis of transition risks and opportunities is to go beyond the narrative of stranded assets and to consider a classification of sectors of all the economic activities

that could be affected (Monasterolo 2020). This, in turn depends on their direct or indirect role in the GHG value chain, their level of substitutability with respect to fossil fuel and their role in the policy landscape. Moreover, such a classification needs to be replicable and comparable across portfolios and jurisdictions. One classification that meets these criteria is the Climate Policy Relevant Sectors (CPRS) (Battiston et al. 2017) which has been used in several studies by financial supervisors (EIOPA 2018; ECB 2019; EBA 2020; ESMA 2020). The CPRS classification builds on the international classification of economic activities (ISIC) to map the most granular level (4 digits) into a small set of categories characterised by differing types of risk: fossil fuel (i.e., all activities whose revenues depend mostly and directly on fossil fuel, including concession of reserves and operating industrial plants for extraction and refinement); electricity (affected in terms of input but that can in principle diversify their energy sources); energy intensive (e.g., steel or cement production plants, automotive manufacturing plants), which are affected in terms of energy cost but not in terms of the main input); and transport and buildings (affected in terms of both energy sources and specific policies). All financial assets (e.g., bonds, equity shares, loans) having as issuers or counterparties firms whose revenues depend significantly on the above activities are thus potentially exposed to transition risks and opportunities. Further, investors' portfolios have to be part of the analysis since changes in financial assets values affect the stability of financial institutions and can thus feed back into the transition dynamics itself (e.g., through cost of debt for firms and through costs for assisting the financial sector). One outstanding challenge for the analysis of investors' exposure to climate risks is the difficulty of gathering granular and standardised information on the breakdown of non-financial firms' revenues and CAPEX in terms of low-/high-carbon activities (*high confidence*).

Several financial supervisors have conducted assessments of transition risk for the financial system at the regional level. For instance, the European Central Bank (ECB) reported preliminary estimates of aggregate exposures of financial institutions to CPRS relative to their total debt securities holdings as ranging between 1% for banks to about 9% for investment funds (ECB 2019). The European Insurance and Occupational Pensions Authority (EIOPA) reported aggregate exposures to CPRS of EU insurance companies at about 13% of their total securities holdings (EIOPA 2018). Further analyses on the EU securities holdings indicate that among financial investments in bonds issued by non-financial corporations, EU institutions hold exposures to CPRS ranging between 36.8% for investment funds to 47.7% for insurance corporations; analogous figures for equity holdings range from 36.4% for banks to 43.1% for pension funds (Alessi et al. 2019). Another study indicates that losses on EU insurance portfolios of sovereign bonds could reach up to 1%, in conservative scenarios (Battiston et al. 2019).

Given the magnitude of the assets that are potentially exposed, reported in the previously cited studies, a delayed or uncoordinated transition risk can have implications for financial stability not only at the level of individual financial institutions, but also at the macro level. The possible systemic nature of climate financial risk has been highlighted on the basis of general equilibrium economic analysis (Stern and Stiglitz 2021).

Some financial authorities recognise that climate change represents a major source of systemic risk, particularly for banks with portfolios concentrated in certain economic sectors or geographical areas (de Guindos 2021). Specifically, the concern that central banks would have to act as 'climate rescuers of last resort' in a systemic financial crisis stemming from some combination of physical and transition risk has been raised in the financial supervisor community (Bolton et al. 2020). The systemic nature of climate risk is reinforced by the possible presence of moral hazard. Indeed, if a sufficient number of financial actors have an incentive to downplay climate-related financial risk, then systemic risk builds up in the financial system, eventually materialising for taxpayers (Climate-Related Market Risk Subcommittee 2020). While such type of risk may go undetected to standard market indicators for a while, it can materialise with a time delay, similarly to the developments observed in the run up to the 2008 financial crisis.

These considerations are part of an ongoing discussion on whether the current financial frameworks, including Basel III, should incorporate explicitly climate risk as a systemic risk. In particular, the challenges in quantifying the extent of climate risk, reviewed in this section, especially if risk is systemic, raise the question whether a combination of quantitative and qualitative restrictions on banks' portfolios could be put in place to limit the build-up of climate risks (Baranović et al. 2021).

Endogeneity of risk and multiplicity of scenarios. One fundamental challenge is that climate-related financial risk is endogenous (*high confidence*). This means that the perception of the risk changes the risk itself, unlike most contexts of financial risk. Indeed, transition risk depends on whether governments and firms continue on a business-as-usual pathway (i.e., misaligned with the Paris Agreement targets) or engage on a climate mitigation pathway. But the realisation of the transition pathway depends itself on how, collectively, society, including financial investors and supervisors, perceive the risk of taking or not taking the transition scenario. The circularity between perception of risk and realisation of the scenario implies that multiple scenarios are possible, and that which scenario is ultimately realised can depend on policy action. The coordination problem associated also with low-carbon investments opportunities increases the uncertainty. Further, not all low-carbon activities are directly functional to the transition (e.g., investments in pharmaceutical, IT companies, or financial intermediaries), thus not all reallocations of capital lead to the same path.

In this context, probabilities of occurrence of scenarios are difficult to assess and this is important because risks vary widely across the different scenarios. In this context a major challenge is the fat-tail nature of physical risk. On the one hand, forecasts of climate change and its impact on humans and ecosystems imply tail events (Weitzman 2014) and tipping points which cannot be overcome by model consensus (Knutti 2010). On the other hand, everything else the same, costs and benefits vary substantially with assumptions on agents' utility, productivity, and intertemporal discount rate, which ultimately depend on philosophical and ethical considerations (Nordhaus 2007; Stern 2008; Pindyck 2013). Thus, more knowledge is needed on the interaction of climate physical and transition risks,

the possible reinforcing feedbacks and transmission channels to the economy and to finance. Moreover, models need to account for compound risk, that is, the interaction of climate physical and/or transition risk with other sources of risk such as pandemics, such as COVID-19.

Challenges for climate transition scenarios. The endogeneity of risk and its associated deep uncertainty implies that the standard approach to financial risk, consisting of computing expected values and risk based on historical values of market prices, is not adequate for climate risk (*high confidence*) (Bolton et al. 2020). To address this challenge, a recent stream of work has developed an approach to make use of climate policy scenarios to derive risk measures (e.g., expected shortfall) for financial assets and portfolios, conditioned to scenarios of disorderly transition (Battiston et al. 2017; Monasterolo and Battiston 2020; Roncoroni et al. 2020). In particular, climate policy shocks on the output of low-/high-carbon economic activities are calculated based on trajectories of energy technologies as provided by large-scale Integrated Assessment Models (Kriegler et al. 2015; McCollum et al. 2018) conditioned to the introduction of specific climate policies over time. This approach allows to conduct climate stress-tests both at the level of financial institutions and at the level of the financial system of a given jurisdiction.

In a similar spirit, recently, the community of financial supervisors in collaboration with the community of climate economics has identified a set of climate policy scenarios, based on large-scale IAM, as candidate scenarios for assessing transition risk (Monasterolo and Battiston 2020). These scenarios have been used, for instance, in an assessment of transition risk conducted at a national central bank (Allen et al. 2020). This development is key to mainstreaming the assessment of transition risk among financial institutions, but the following challenges emerge (*high confidence*). First, a consensus among financial supervisors and actors on scenarios of transition risk that are too mild could lead to a systematic underestimation of risk. The reason is that the default probability of leveraged financial institutions is sensitive to errors in the estimation of the loss distribution and hence sensitive on the choice of transition scenarios (Battiston and Monasterolo 2020). This in turn could lead to an allocation of capital across low-/high-carbon activities that is insufficient to cater for the investment needs of the low-carbon transition.

Second, IAM do not contain a description of the financial system in terms of actors and instruments and make assumptions on agents' expectations that could be inconsistent with the nature of a disorderly transition (Espagne 2018; Pollitt and Mercure 2018a; Battiston et al. 2020b). In particular, IAMs solve for least cost pathways to an emissions target in 2100 (AR4 WGIII SPM Box 3), while the financial sector's time horizon is much shorter and risk is an important factor in investment decisions.

Third, the current modelling frameworks used to develop climate mitigation scenarios, which are based on large-scale IAM, assume that the financial system acts always as an enabler and do not account for the fact that, under some condition (i.e., if there is underestimation of climate transition risk) can also act as a barrier to the transition

(Battiston et al. 2020a) because it invests disproportionately more in high-carbon activities.

Macroeconomic implications of the technological transition.

Global macroeconomic changes that may affect asset prices are expected to take place as a result of a possible reduction in growth or contraction of fossil fuel demand, in scenarios in which climate targets are met according to carbon budgets, but also following ongoing energy efficiency changes (*high confidence*) (Clarke et al. 2014; Mercure et al. 2018a). A review of the economic mechanisms involved in the accumulation of systemic risk associated with declining industries, with focus on fossil fuels, is given by Semieniuk et al. (2021). An example is the transport sector, which uses around 50% of oil extracted (IEA 2018; Thomä 2018). A rapid diffusion of EV (and other alternative vehicle types) poses an important risk as it could lead to oil demand peaking far before mid-century (Mercure et al. 2018b; 2021). New technologies and fuel switching in aviation, heavy industry and shipping could further displace liquid fossil fuel demand (IEA 2017). A rapid diffusion of solar photovoltaic could displace electricity generation based predominantly on coal and gas (Sussams and Leaton 2017). A rapid diffusion of household and commercial indoor heating and cooling based on electricity could further reduce the demand for oil, coal and gas (Knobloch et al. 2019). Parallels can be made with earlier literature on great waves of innovation, eras of clustered technological innovation and diffusion between which periods of economic, financial and social instability have emerged (Freeman and Louca 2001; Perez 2009).

Due to the predominantly international nature of fossil fuel markets, assets may be at risk from regulatory and technological changes both domestically and in foreign countries (*medium confidence*). Fossil fuel exporting nations with lower competitiveness could lose substantial amounts of industrial activity and employment in scenarios of peaking or declining demand for fossil fuels. In scenarios of peaking oil demand, production is likely to concentrate towards the Middle East and OPEC countries (IEA 2017). Since state-owned fossil fuel companies tend to enjoy lower production costs, privately-owned fossil fuel companies are more at risk (Thomä 2018). Losses of employment may be directly linked to losses of fossil fuel-related industrial activity or indirectly linked through losses of large institutions, notably of government income from extraction royalties and export duties. A multiplier effect may take place making losses of employment spill out of fossil fuel extraction, transformation and transportation sectors into other supplying sectors (Mercure et al. 2018a).

Main regulatory developments and voluntary responses to climate risk. Framing climate risk as a financial risk (not just as an ethical issue) is key for it to become an actionable criterion for investment decision among mainstream investors (*high confidence*) (TCFD 2019). Since 2015 financial supervisors and central banks (e.g., the Financial Stability Board, the G20 Green Finance Study Group, and the Network for Greening the Financial System (NGFS)) have played a central role in raising awareness and increasing transparency of the potential material financial impacts of climate change within the financial sector (Bank of England 2015, 2018; TCFD 2019). The NGFS initiative has engaged, in particular, in the elaboration of climate financial risk scenarios.

Although disclosure has increased since the TCFD recommendations were published, the information is still insufficient for investors and more clarity is needed on potential financial impacts and how resilient corporate strategies are under different scenarios (TCFD 2019). Several efforts to provide guidance and tools for the application of the TCFD recommendations have been made (using Sustainability Accounting Standards Board (SASB) Standards and the Climate Disclosure Standards Board (CDSB) Framework to Enhance Climate-Related Financial Disclosures in Mainstream Reporting TCFD Implementation Guide (UNEP FI 2018; CDSB and SASB 2019). Results of voluntary reporting have been mixed, with one study pointing to unreliable and incomparable results reported by the US utilities sector to the CDP (Stanny 2018).

There have been also similar initiatives at the national level (DNB 2017; UK Government 2017; US GCRP 2018b). In particular, France was the first country to mandate climate risk disclosure from financial institutions (via Article 173 of the law on energy transition). However, disclosure responses have been so far mixed in scope and detail, with the majority of insurance companies not reporting on physical risk (Evain et al. 2018). In the UK, mandatory GHG emissions reporting for UK-listed companies has not led to substantial emissions reductions to date but could be laying the foundation for future mitigation (Tang and Demeritt 2018).

A key recent development is the EU Taxonomy for Sustainable Finance (TEG 2019), which provides a classification of economic activities that (among other dimensions) contribute to climate mitigation or can be enabling for the low-carbon transition. Indirectly, such classification provides useful information on investors' exposure to transition risk (Alessi et al. 2019; ESMA 2020). Finally, many consultancies have stepped forward offering services related to climate risk. However, the methods are typically proprietary, non-transparent, or based primarily on carbon footprinting, which is a necessary but insufficient measure of climate risk. Further, ESG (environmental, social and governance) metrics can be useful but are, alone, inadequate to assess climate risk.

Illustrative mitigation pathways and financial risk for end-users of climate scenarios

Decision-makers in financial risk management make increasing use of climate policy scenarios, in line with the TCFD guidelines and the recommendations of the NGFS. In order to reduce the number of scenarios to consider, Illustrative Mitigation Pathways (IMPs, Chapter 3), have been elaborated to illustrate key features that characterise the possible climate (policy) futures. The following considerations can be useful for scenario end-users who carry out risk analyses on the basis of the scenarios described in Chapter 3. It is possible to associate climate policy scenarios with levels of physical and/or transition risk, but these are not provided with the scenario data themselves.

On the one hand, each scenario is associated with a warming path, which in turn, on the basis of the results from WGII, implies certain levels of physical risk (AR6 WGII Chapter 16). However, climate impacts are not accounted for in the scenarios. Moreover, levels of risk may vary

with the reason for concern and with the speed of the implementation of adaptation. On the other hand, while mitigation can come with transition risk, in the case of lack of coordination among the actors, as discussed earlier in this section, this is not modelled explicitly in the trajectories, since the financial sector is not represented in underlying models. The scientific state of the art in climate-related financial risk offers an analysis that is not yet comprehensive of both the physical and transition risk dimensions in the same quantitative framework. However, decision-makers can follow a mixed approach where they can combine quantitative risk assessment for transition risk with more qualitative risk analysis related to physical risk.

Figure 15.6 represents sequences of events following along a scenario both in terms of physical risk (left) and transition risk (right). Four groups of IMPs (more are considered based on the warming level they lead to in 2100. Current Policies (CurPol) considers climate policies implemented in 2020 with only a gradual strengthening afterwards, leading to above 4°C warming (with respect to pre-industrial levels). Moderate Action (ModAct) explores the impact of implementing the NDCs (pledged mitigation targets) as formulated in 2020 and some further strengthening afterwards, thereby limiting warming to less than 4°C (>50%), but above 3°C (>50%). In these two scenarios, there is no stabilisation of temperature, meaning that further warming occurs after 2100 (and higher risk) even if stabilisation could be eventually achieved. They are referred to as

pathways with higher emissions. The warming levels reached along these two scenarios imply physical risk levels that are 'Moderate' until 2050 and 'Very High' in 2050–2100 (with low levels of adaptation). Noting, that 'Moderate' physical risk can mean for some countries (i.e., SIDS) significant and even hardly absorbable consequences (i.e., reaching hard adaptation limits). Transition risk is not relevant for these scenarios, since a transition is not pursued.

Illustrative Mitigation Pathways include two groups of scenarios consistent with modelled global pathways that limit warming to 2°C (>67%) or lower, respectively. The two groups are representative for the IMPs defined in Chapter 3. In these scenarios, warming is stabilised before 2100. The warming levels along these paths imply 'Moderate' physical risk until 2050 and 'High' risk in 2050–2100 (with low levels of adaptation). Transition risk can arise along these trajectories from changes in expectations of economic actors about which of the scenarios is about to materialise. These changes imply, in turn, possible large variations in the financial valuation of securities and contracts, with losses on the portfolio of institutional investors and households. High policy credibility is key to avoiding transition risk, by making expectations consistent early on with the scenario. Low credibility can delay the adjustment of expectations by several years, leading either to a late and sudden adjustment. However, if the policy never becomes credible, this changes the scenario since the initial target is not met.

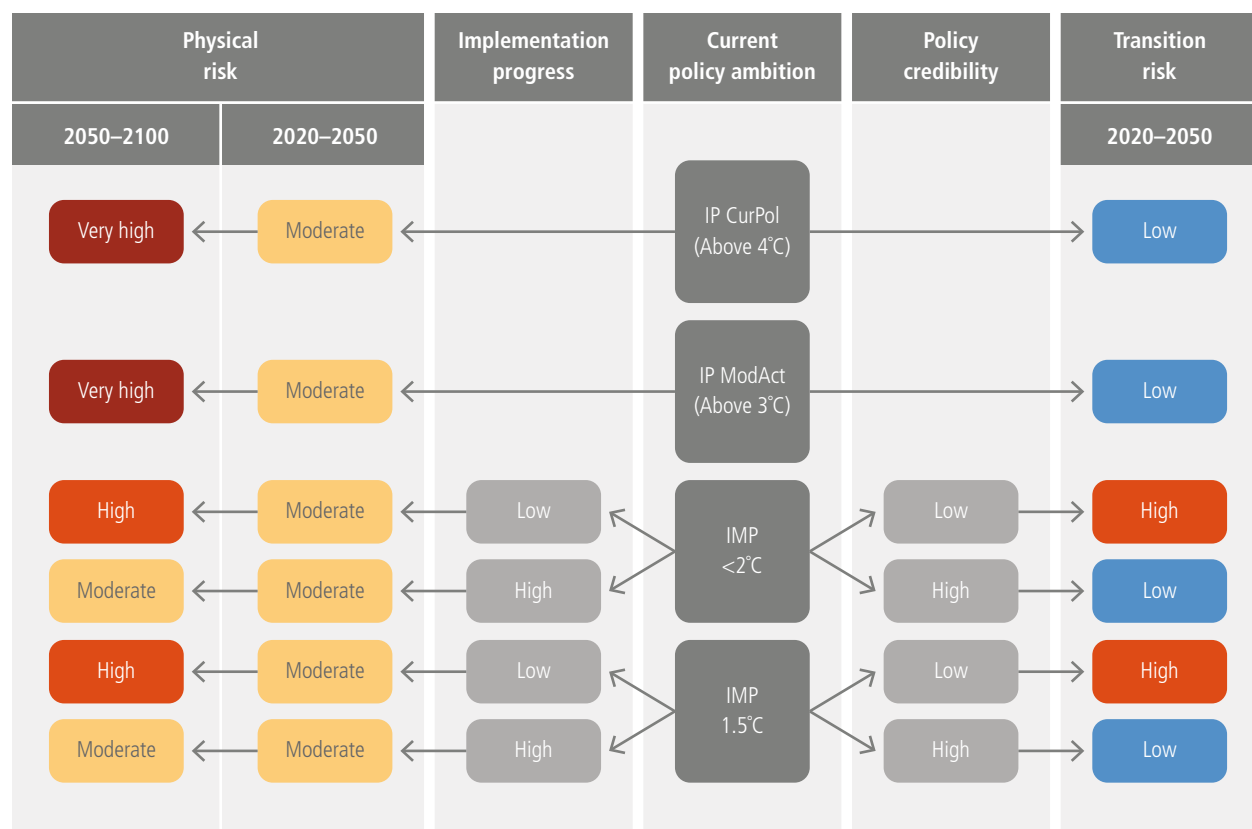

Figure 15.6 | Schematic representation of climate scenarios in terms of both physical and transition risk. While the figure does not cover all possible events, it maps out how the combination of stated targets can lead to different paths in terms of risk, depending on implementation progress and policy credibility. IMP 1.5°C and IMP <2°C are representative for IMP-GS (Sens. Neg; Ren), IMP-Neg, IMP-LD; IMP-Ren; IMP-SP. Note that the figure defines 'High' progress as higher, but it is important that the physical risk varies by region and country. This means, that 'Moderate' physical risk can be significant and even hardly absorbable for some countries.

15.6.2 Enabling Environments

The Paris Agreement recognised for the first time the key role of aligning financial flows to climate goals. It further emphasises the importance of making financial flows consistent with climate actions and SDGs (Zamarioli et al. 2021). This alignment has now to be operated in a specific environment where the scaling-up of climate policies is conditional upon their contribution to post-COVID-19 recovery packages (Sections 15.2.2 and 15.2.3 and Box 15.6). The enabling environments that are to be established account for the structural parameters of the underinvestment in long-term assets. The persistent gap between the 'propensity to save' and 'propensity to invest' (Summers 2016) obstructs the scaling up of climate investments, and it results from a short-term bias of economic and financial decision-making (Miles 1993; Bushee 2001; Black and Fraser 2002) that returns weighted on short-term risk dominate the investment horizon of financial actors. Overcoming this bias is the objective of an enabling environment apt to *launch of a self-reinforcing circle of trust* between project initiators, industry, institutional investors, the banking system, and governments.

The role of government is crucial for creating an enabling environment for climate (Clark 2018), and governments are critical in the launching and maintenance of this circle of trust by lowering the political, regulatory, macroeconomic and business risks (*high confidence*). The issue is not just to progressively enlarge the space of low-carbon investments but to replace one system (fossil fuels energy system) rapidly with another (low-carbon energy system). This is a wave of 'creative destruction' with the public support for developing new markets and new entrepreneurship and finance for green products and technologies in a context which requires strong complementarities between Schumpeterian (technological) and Keynesian (demand-related) policies (Dosi et al. 2017). However, it is challenging to overcome the constraint of public budget under the pressure of competing demands and of creditworthy constraints for countries that do not have an easy access to reserve currencies. It is needed to maximise, both at the national and international levels, the leverage ratio of public funds engaged in blended finance for climate change which is currently very low, especially in developing countries (Attridge and Engen 2019).

Transparency: Policy de-risking measures, such as robust policy design and better transparency, as well as financial de-risking measures, such as green bonds and guarantees, at both domestic and international levels, enhance the attractiveness of clean energy investments (*high confidence*) (Steckel and Jakob 2018). Organisations such as the Task Force on Climate-related Financial Disclosures (TCFD) can help increase capital markets' climate financing, including private sector, by providing financial markets with information to price climate-related risks and opportunities (TCFD 2020). However, risk disclosures alone would likely be insufficient as long as market failures that inhibit the emergence of low-carbon investment initiatives with positive risk-weighted returns (*high confidence*) (Christophers 2017; Ameli et al. 2020).

Central banks and climate change. Central banks in all economies will likely have to play a critical role in supporting the financing

of fiscal operations, particularly in a post-COVID-19 world (*high confidence*). Instruments and institutional arrangements for better international monetary policy coordination will likely be necessary in the context of growing external debt stress and negative credit rating pressures facing both emerging and low-income countries. Central bankers have started examining the implications of disruptive risks of climate change, as part of their core mandate of managing the stability of the financial system (Chenet et al. 2021). Climate-related risk assessments and disclosure, including central banks' stress testing of climate change risks, can be considered as a first step (Rudebusch 2019), although such risk assessments and disclosure may not be enough by themselves to spur increased institutional low-carbon climate finance (Ameli et al. 2020).

Green quantitative easing (QE) is now being examined as a tool for enabling climate investments (Dafermos et al. 2018) in which central banks could explicitly conduct a programme of purchases of low-carbon assets (Aglietta et al. 2015). A green QE programme 'would have the benefit of providing large amounts of additional liquidity to companies interested' in green projects (*medium confidence*) (Campiglio et al. 2018). Green QE would have positive effects for stimulating a low-carbon transition, such as accelerating the development of green bond markets (Hilmi et al. 2021), encouraging investments and banking reserves, and reducing risks of stranded assets, while it might increase income inequality and financial instability (Monasterolo and Raberto 2017). While the short-term effectiveness would not be substantial, the central bank's purchase of green bonds could have a positive effect on green investment in the long run (Dafermos et al. 2018). However, the use of green QE needs to be cautious on potential issues, such as undermining the central bank's independence, affecting the central bank's portfolio by including green assets with poor financial risk standards, and potential regulatory capture and rent-seeking behaviours (Krogstrup and Oman 2019).

Additional monetary policies and macroprudential financial regulation may facilitate the expected role of carbon pricing on boosting low-carbon investments (*medium confidence*) (D'Orazio and Popoyan 2019). Commercial banks may not respond to the price signal and allocate credits to low-carbon investments due to the existence of market failure (Campiglio 2016). This could support the productivity of green capital goods and encourage green investments in the short term, but might cause financial instability by raising non-performing loans ratio of dirty investments and creating green bubbles (Dunz et al. 2021). Financial supervisors need to implement stricter guidelines to overcome the greenwashing challenges (Caldecott 2020).

Efficient financial markets and financial regulation. An influential efficient financial markets hypothesis (Fama 1970, 1991, 1997) proceeds from the assumption that in well-developed financial markets, available information at any point of time is already well captured in capital markets with many participants. Despite increasing challenges to the theory (Sewell 2011), especially by repeated episodes of global financial crashes and crises, and other widely noted anomalies, a weaker form of the efficient markets hypothesis may still apply (*medium confidence*). It is arguable that accumulating

scientific evidence of climate impacts is being accompanied by rising levels of climate finance. Banks and institutional investors are also progressively rebalancing their investment portfolios away from fossil fuels and towards low-carbon investments (IEA 2019b; Monasterolo and de Angelis 2020). In the meantime, the world runs the risk of sharp adjustments, crises and irreversible ‘tipping points’ (Lontzek et al. 2015) sufficiently destabilising climate outcomes. This leads to the policy prescription towards financial regulatory agencies requiring greater and swifter disclosure of information about rising climate risks faced by financial institutions in projects and portfolios and central bank attention to systemic climate risk problems as one possible route of policy action (Carney 2015; Dietz et al. 2016; Zenghelis and Stern 2016; Campiglio et al. 2018). However, disclosure requirements of risks and information in private settings remain mostly voluntary and difficult to implement (Battiston et al. 2017; Monasterolo et al. 2017).

Nevertheless, financial markets are innovating in search of solutions (Section 15.6.6). Recognising and dealing with stranded fossil fuel assets is also a key area of growing concern that financial institutions are beginning to grapple with. Larger institutions with more patient capital (pensions, insurance) are also increasingly beginning to enter the financing of projects and green bond markets. The case for efficient financial markets in developing countries is worse (Abbasi and Riaz 2016; Hong et al. 2019) because of weaker financial institutions (Hamid et al. 2017), heightened credit rationing behaviour (Bond et al. 2015), and high risk aversion as most markets are rated as junk, or below/barely investment grade (Hanusch et al. 2016). Other constraints such as limited long-term financial instruments and underdeveloped domestic capital markets, absence of significant domestic bond markets for investments other than sovereign borrowing, and inadequate term and tenor of financing, make the efficient markets thesis practically inapplicable for most developing countries.

Markets, finance and creative destruction. Branches of macro-innovation theory could be grouped into two principal classes (Mercure et al. 2016): ‘equilibrium – optimisation’ theories that treat innovators as rational perfectly informed agents and reaching equilibrium under market price signals; and ‘non-equilibrium’ theory where market choices are shaped by history and institutional forces and the role of public policy is to intervene in processes, given a historical context, to promote a better outcome or new economic trajectory. The latter suggests that new technologies might not find their way to the market without price or regulatory policies to reduce uncertainty on expected economic returns. A key issue is the perception of risk by investors and financial institutions. The financial system is part of complex policy packages involving multiple instruments (cutting subsidies to fossil fuels, supporting clean energy innovation and diffusion, levelling the institutional playing field and making risks transparent) (Polzin 2017) and the needed big systemic push (Kern and Rogge 2016) requires it takes on the role of ‘institutional innovation intermediaries’ (Polzin et al. 2016).

As far as climate finance is concerned, public R&D support had large cross-border knowledge spill-overs indicating that openness

to trade was important, capacity expansion had positive effects on learning-by-doing on innovation over time, and that feed-in-tariffs (FITs), in particular, had positive impacts on technology diffusion (Grafström and Lindman 2017) (Box 16.4). The FITs programme has been associated with rapid increase in early renewables capacity expansion across the world by reducing market risks in financing and stability in project revenues (Menanteau et al. 2003; Jacobsson et al. 2009) (Section 9.9.5). Competitive auctions where the bidder with the lowest price or other criteria is selected for government’s call for tender are increasingly being utilised as an alternative to FITs due to their strengths of flexibility, potential for real price discovery, ability to ensure greater certainty in price and quantity, and capability to guarantee commitments and transparency (IRENA and CEM 2015).

Outside of renewable energy, scattered but numerous examples are available on the role of innovative public policy to spur and create new markets and technologies (Arent et al. 2017): (i) proactive role of the state in energy transitions (e.g., the retirement of all coal-fired power plants in Ontario, Canada, between 2007 and 2014 (Kern and Rogge 2016; Sovacool 2016)); (ii) too early exit and design problems not considering the market acceptability and financing issues (e.g., energy-efficient retrofitting in housing in UK (Rosenow and Eyre 2016), low or negative returns in reality versus engineering estimates in weatherisation programmes in US (Fowlie et al. 2018)); and (iii) energy performance contracting for sharing the business risks and profits and improving energy efficiency (energy service companies (Bertoldi and Boza-Kiss 2017; Qin et al. 2017) and utility energy service contracts in the USA (Clark 2018)).

Crowding out. Literature has discussed the risks of low effectiveness of public interventions and of a crowding out effect of climate-targeted public support to other innovation sectors (Buchner et al. 2013). However, much academic literature suggests no strong evidence of crowding out. (Deleidi et al. 2020). Examining the effect of public investment on private investment into renewables in 17 countries over 2004–2014, showed that the concept of crowding out or in does not apply well to sectoral studies and found that public investments positively support private investments in general.

Support climate action via carbon pricing, taxes, and emission trading systems. Literature and evidence suggest that futures markets regarding climate are incomplete because they do not price in externalities (Scholtens 2017). As a result, low-carbon investments do not take place to socially and economically optimal levels, and the correct market signals would involve setting carbon prices high enough or equivalent trading in reduced carbon emissions by regulatory action to induce sufficient and faster shift towards low-carbon investments (*high confidence*) (Aghion et al. 2016). Nonetheless, durable carbon pricing in economic and political systems must be implemented and approached combining related elements to both price and quantity (Grubb 2014).

The introduction of fiscal measures, such as carbon taxes, or market-based pricing, such as emission trading schemes, to reflect carbon pricing have benefits and drawbacks that policymakers need to consider, taking account of both country-specific conditions and

policy characteristics. Carbon tax can be a simpler and easier way to implement carbon pricing, especially in developing countries, because countries can utilise the existing fiscal tools and do not need concrete enabling conditions as market-based frameworks (*high confidence*). The reallocation of revenues from carbon taxes can be used for low-carbon investments, supporting poorer sections of society and fostering technological change (High-Level Commission on Carbon Prices 2017). In combination with other policies, such as subsidies and public R&D on resource-saving technologies, properly designed carbon taxes can facilitate the shift towards low-carbon, resource-efficient investments (Bovari et al. 2018; Naqvi and Stockhammer 2018; Dunz et al. 2021) (Section 9.9.3). The effectiveness of carbon pricing has been supported by various evidence. EU ETS has cut emissions by 42.8% in the main sectors covered (European Commission 2021a), and China had achieved emissions reductions and energy conservation through its pilot ETS between 2013 and 2015 (Zhang et al. 2019; Hu et al. 2020). Institutional learning, administrative prudence, appropriate carbon revenue management and stakeholder engagement are key ingredients for successful ETS regimes (Narassimhan et al. 2018).

The presence of carbon prices can promote low-carbon technologies and investments (Best and Burke 2018), and price signals, including carbon taxation, provide powerful and efficient incentives for households and firms to reduce CO₂ emissions (IMF 2019). The expansion of carbon prices is dependent on country-specific fiscal and social policies to hedge against regressive impacts on welfare, competitiveness, and employment (Michaelowa et al. 2018). Such impacts need to be offset using the proceeds of carbon taxes or auctioned emission allowances to reduce distortive taxation (Bovenberg and de Mooij 1994; Goulder 1995; de Mooij 2000; Chiroleu-Assouline and Fodha 2014) and fund compensating measures for the population sections that are most adversely impacted (Combet et al. 2010; Jaccard 2012; Klenert et al. 2018). This is more difficult for developing countries with a large share of energy-intensive activities, fossil fuel exporting countries and countries which have lower potential to mitigate impacts due to lower wages or existing taxes (Lefèvre et al. 2018).

Non-carbon price instruments, such as market-oriented regulation and public programmes involving low-carbon infrastructure, may be preferable in developing countries where market and regulatory failure and political economy constraints are more prevalent (Finon 2019). While carbon pricing was suggested by many economists and researchers (Nordhaus 2015; Pahle et al. 2018), overcoming the political and regulatory barriers would be necessary for the further implementation of an effective carbon pricing scheme nationally and internationally. Without strong political support, the effectiveness of carbon pricing would be limited to least-cost movements (Meckling et al. 2015).

Role of domestic financing sources. Efforts to address climate change can be scaled up through the mobilisation of domestic funds (Fonta et al. 2018). Publicly organised and supported low-carbon infrastructures through resurrected national development banks may be justified (Mazzucato and Penna 2016). It is important

to efficiently allocate the public financing, and State Investment Banks (SIBs) can take up key roles (i) to provide capital to assist with overcoming financial barriers, (ii) to signal and direct investments towards green projects, and (iii) to attract private investors by taking up a de-risking role. Also, they can become a first mover by investing in new and innovative technologies or business models (Geddes et al. 2018). State-owned enterprises (SOEs) can also have an overall positive effect on renewables investments, outweighing any effect of crowding out private competitors (Prag et al. 2018). Green investment banks can assist in the green transition by developing valuable expertise in implementing effective public interventions to overcome investment barriers and mobilise private investment in infrastructure (OECD 2015c). De-risking measures may reduce investment risks, but lacking research and data availability hinders designing such measures (Dietz et al. 2016). Local governments' efforts to de-risk by securitisation might have negative effects by narrowing the scope for a green developmental state and encouraging privatisation of public services (Gabor 2019).

The potential role of coordinated multilateral initiatives.

There is a growing awareness of the low leverage ratio of public to private capital in climate blended finance (Blended Finance Taskforce 2018b) and of a 'glass ceiling', caused by a mix of agencies' inertia and perceived loss of control over the use of funds, on the use of public guarantees by MDBs to increase it (*high confidence*) (Gropp et al. 2014; Schiff and Dithrich 2017; Lee et al. 2018). Many proposals have emerged for multilateral guarantee funds: Green Infrastructure Funds (de Gouvello and Zelenko 2010; Studart and Gallagher 2015), Multilateral Investment Guarantee Agency (Enhanced Green MIGA) (Déau and Touati 2018), guarantee funds to bridge the infrastructure investment gap (Arezki et al. 2016), and multi-sovereign guarantee mechanisms (Dasgupta et al. 2019). The obstacle of limited fiscal space for economic recovery and climate actions in low-income and some emerging economies can be overcome only in a multilateral setting. Several multilateral actions are being envisaged: G20's suspension of official bilateral debt payments, IMF's adoption of new SDRs allocation (IMF 2021b). However, any form of unconventional debt relief will generate development and climate benefits only if they credibly target bridging the countries' infrastructure gap with low-carbon climate-resilient options.

Of interest in multilateral settings is a credibility-enhancing effect provided by reciprocal gains for both the donor and the host country. Guarantor countries can compensate the public cost of their commitments with the fiscal revenues of induced exports. As to the host countries, they would benefit from new capital inflows and the grant equivalents of reduced debt service which might potentially go far beyond USD100 billion yr⁻¹ (Hourcade et al. 2021a). A second interest would be to support a learning process about agreed-upon assessment and monitoring methods using clear metrics. Developing standardised and science-based assessment methods at low transaction costs is essential to strengthen the credibility of green investments and the emergence of a pipeline of high-quality bankable projects which can be capitalised in the form of credible assets and supported with transparent and credible domestic spending. Multi-sovereign guarantees would provide a quality backing to developing

Box 15.5 | The Role of Enabling Environments for Decreasing Economic Cost of Renewable Energy

A widely used indicator for the relative attractiveness of renewable energy but also development of price levels is the levelised cost of energy (LCOE). It is applied by a wide range of public and private stakeholders when tracking progress with regard to cost degression (Aldersey-Williams and Rubert 2019). LCOE calculation methodologies vary but in principle consider project-level costs only (NEA 1989). Besides other weaknesses, the LCOE concept usually does not consider societal costs resulting from de-risking instruments and/or other public interventions/support and therefore caution has to be applied when using the LCOE as the sole indicator of the success of enabling environments. The yearly IRENA mapping on renewable energy auction results demonstrates the extremely broad ranges of LCOEs (equal to the agreed tariffs) for renewable energy which can be observed (IRENA 2019a). For example, in 2018, solar PV LCOEs for utility-scale projects came in between USD0.04 kWh⁻¹ and USD0.35 kWh⁻¹ with a global weighted average of USD0.085 kWh⁻¹. However, comparative analysis taking into account societal costs is hardly available driven by challenges in the context of the quantification of public support.

The GET FiT concept argued that the mitigation of political and regulatory risk by sovereign and international guarantees is cost-efficient in developing countries, illustrating the estimated impact of such risk-mitigation instruments on equity and debt financing costs, and consequently required feed-in tariff levels (Deutsche Bank Climate Change Advisors 2011). The impact of financing costs on cost of renewable energy generation is well researched with significant differences across countries and technologies being observed, with major drivers being the regulatory framework as well as the availability and type of public support instruments (Geddes et al. 2018; Steffen 2019). With a focus on developing countries and based on a case study in Thailand Huenteler et al. (2016) demonstrate the significant effect of regulatory environments but also local learning and skilled workforce on cost of renewables. The effect of those exceeds the one of global technology learning curves.

Egli et al. (2018) identify macroeconomic conditions (general interest rate) and experience effects within the renewable energy finance industry as key drivers in developed countries with a stable regulatory environment, contributing 5% (PV) and 24% (wind) to the observed reductions in LCOEs in the German market with a relatively stable regulatory environment. They conclude that 'extant studies may overestimate technological learning and that increases in the general interest rate may increase renewable energies' LCOEs, casting doubt on the efficacy of plans to phase out policy support' (Egli et al. 2018). A rising general interest rate level could heavily impact LCOEs – for Germany, a rise of interest rates to pre-financial crisis levels in five years could increase LCOEs of solar and wind by 11–25% respectively (Schmidt et al. 2019).

countries and allow for expanding developing countries' access to capital markets at a lower cost and longer maturities, overcome the Basel III's liquidity impediment and the EU's Solvency II directive on liquidity (Blended Finance Taskforce 2018b), and accelerate the recognition of climate assets by investors seeking safe investment havens (Hourcade et al. 2021b). They would also strengthen the efficacy of climate disclosure through high grades climate assets and minimise the risks of 'greening' of the portfolios by investing in 'carbon neutral' activities and not in low-carbon infrastructures. Finally, they would free up grant capacities for SDGs and adaptation that mostly involve non-marketable activities by crowding in private investments for marketable mitigation activities.

15.6.2.1 The Public-Private and Mobilisation Narrative and Current Initiatives

Financing by development finance institutions and development banks aims to address market failures and barriers related to limited access to capital as well as provide direct and indirect subsidisation by accepting higher risk, longer loan tenors and/or lower pricing. Many development and climate projects in developing and emerging countries have traditionally been supported with concessional loans

by development finance institutions and/or international financial institutions (DFIs/IFIs). With an increasing number of sectors becoming viable and increasing complaints of private sector players with regard to crowding out (Bahal et al. 2018), a stronger separation and crowding in of commercial financing at the project/asset level is targeted. MDBs and IFIs were crucial for opening and growth in the early years of the green bonds, which represent a substantial share of issuances (CBI 2019a). Drivers of an efficient private sector involvement are stronger incentives to have projects delivered on time and in budget as well as market competition (Hodge et al. 2018). It remains key that the private sector mobilisation goes hand in hand with institutional capacity building as well as strong sectoral development in the host country, as a strong, knowledgeable public partner with the ability to manage the private sector is a dominating success factor for public-private cooperation (WEF 2013; Yescombe 2017; Hodge et al. 2018).

Limited research is available on the efficiency of mobilisation of the private sector at the various levels and/or the theory of change attached to the different approaches as applied in classical public-private partnerships. Also, transparency on current flows and private involvement at the various levels is limited with no differentiation

being made in reporting (e.g., GCF co-financing reporting). Limited prioritisation and agreement on prioritisation of sectors and/or project categories being ready and/or preferred for direct private sector involvement might become a challenge in the coming years (*high confidence*) (Sudmant et al. 2017a; Sudmant et al. 2017b).

Public guarantees have been increasingly proposed to expand climate finance, especially from the private sector, with scarce public finance, by reducing the risk premium of the low-carbon investment opportunities (de Gouvello and Zelenko 2010; Emin et al. 2014; Studart and Gallagher 2015; Schiff and Dithrich 2017; Lee et al. 2018; Steckel and Jakob 2018). They have the advantage of a broad coverage including the 'macro' country risks and to tackle the up-front risks during the preparation, bidding and development phases of the project lifecycle that deter project initiators, especially for capital-intensive and immature options. Insurances are also powerful de-risking instruments (Déau and Touati 2018) but they entitle the issuer to review claims concerning events and cannot cope with up-front costs. Contractual arrangements like power purchase agreements are powerful instruments to reduce market risks through a guaranteed price but they weigh on public budgets. Risk-sharing that brings together public agencies, firms, local authorities, private corporates, professional cooperatives, and institutional financiers can reduce costs (UNEP 2011), and support the deployment of innovative business models (Déau and Touati 2018). Combined with emission taxes they can contribute to reducing credit rationing of immature and risky low-carbon technologies (Haas and Kempa 2020).

15.6.3 Considerations on Availability and Effectiveness of Public Sector Funding

The gap analysis as well as other considerations presented in this chapter illustrate the critical role of increased volumes and efficient allocation of public finance to reach the long-term global goals, both nationally and internationally.

Higher public spending levels driven by the impacts of COVID-19 and related recovery packages. Higher levels of public funding represent a massive chance but also a substantial risk. A missing alignment of public funding and investment activity with the Paris Agreement (and Sustainable Development Goals) would result in significant carbon lock-ins, stranded assets and thus increase transition risks and ultimately economic costs of the transition (*high confidence*). Using IMF data for stimulus packages, Andrijevic et al. (2020) estimated that COVID-19-related fiscal expenditure had surpassed USD12 trillion by October 2020 (80% in OECD countries), a third of which being spent in liquidity support and health care. Total stimulus pledged to date is ten times higher than low-Paris-consistent carbon investment needs from 2020–2024 (Andrijevic et al. 2020; Vivid Economics 2020). Overall, stimulus packages launched include USD3.5 trillion to sectors directly affecting future emissions, with overall fossil fuel investment flows outweighing low-carbon technology investment (Vivid Economics 2020).

Lessons from the global financial crises show that although deep economic crises create a sharp short-term emission drop,

and green stimulus is argued to be the ideal response to tackle both the economic and the climate crises at once, disparities between regional strategies hinder the low-carbon transition (*high confidence*). Indeed, inconsistent policies within countries can also counterbalance emission reductions from green stimulus, as well as a lack of transparency and green spending pledged not materialising (Jaeger et al. 2020). Also, aggressive monetary policy as a response to the global financial crisis, including quantitative easing that did not target low-carbon sectors, has been heavily criticised (Jaeger et al. 2020). The COVID-19 crisis recovery, in contrast, benefits from developments which have taken place since, such as an emerging climate-risk awareness from the financial sector, reflected in the call from the Coalition of Finance Ministers for Climate Action (Coalition of Finance Ministers for Climate Action 2020), which unites 50 countries' finance ministers, for a climate-resilient recovery.

The steep decrease in renewable electricity costs since 2010 also represents a relevant driver for a low-carbon recovery (Jaeger et al. 2020). Many more sectors are starting to show similar opportunities for rapid growth with supportive public spending such as low-carbon transport and buildings (IEA 2020d). Expectations that the package will increase economic activity rely on the assumption that increased credit will have a positive effect on demand, the so-called demand-led policy (Mercure et al. 2019). Boosting investment should propel job creation, increasing household income and therefore demand across economic sectors (*high confidence*). A similar plan has also been proposed by the US administration and the European Union through the Next Generation EU (European Council 2020).

Nevertheless, three uncertainties remain. First, only those countries and regions with highest credit-ratings (AAA or AA) with access to deep financial markets and excess savings will be able to mount such counter-cyclical climate investment paths, typically high-income developed economies (*high confidence*). In more debt constrained developing countries lower access to global savings pools because of higher risk perceptions and lower credit ratings (BBB or less), exacerbated by COVID-19, are already leading to credit downgrades and defaults (Kose et al. 2020) and have long tended to be fiscally procyclical (McManus and Ozkan 2015). These include the general class of virtually all major emerging and especially low-income developing countries, to which such demand-stimulating counter-cyclical climate-consistent borrowing path is likely. To access such funds, these countries would need globally coordinated fiscal policy and explicit supporting cross-border instruments, such as sovereign guarantees, strengthening local capital markets and boosting the USD100 billion annual climate finance commitment (Dasgupta et al. 2019).

Second, a strong assumption is that voters will be politically supportive of extended and increased fiscal deficit spending on climate on top of COVID-19-related emergency spending and governments will overcome treasury biases towards fiscal conservatism (to preserve credit ratings). However, evidence strongly suggests that voters (and credit rating agencies) tend to be fiscally conservative (Peltzman 1992; Lowry et al. 1998; Alesina et al. 2011; Borge and Hopland 2020), especially where expenditures involve higher taxes in the future and do not identifiably flow back to their local bases (the 'public good' problem) (*high confidence*). Such mistrust has

been a reason for abortive return to fiscal austerity often in the past (most recently during global financial crisis) and may benefit for political support by consistently reframing the climate expenditures in terms of job creation benefits (Bougrine 2012), effectiveness of least-cost fiscal spending on climate for reviving private activity, and the avoidance of catastrophic losses (Huebscher et. al. 2020) from higher carbon emissions. A new understanding of debt sustainability including negative implications of deferred climate investments on future GDP has not yet been mainstreamed (see

more on the debt sustainability discussion below (e.g., Buhr et al. 2018; Fresnillo 2020a). In addition, implications on the availability of international public finance flows are not yet clear since current additional funding prioritises urgent health care support rather than an increase in predictable mid-/long-term financial support. Heavy investment needs for recovery packages in developed countries on the one hand and their international climate finance commitments on the other might be perceived to compete for available 'perceived as appropriate' budgets.

Box 15.6 | Macroeconomics and Finance of a Post-COVID-19 Green Stimulus Economic Recovery Path

Financial history suggests that capital markets may be willing to accommodate extended public borrowing for transient spending spikes (Barro 1987) when macroeconomic conditions suggest excess savings relative to private investment opportunities (Summers 2015) and when public spending is seen as timely, effective and productive, with governments able to repay when conditions improve as economic crisis conditions abate (*high confidence*). A surge in global climate mitigation spending in the post-pandemic recovery may be an important opportunity, which global capital markets are signalling (Global Investor Statement 2019). The standard 'neo-classical' macroeconomic model is often used in integrated energy-economy-climate assessments (Balint et al. 2016; Nordhaus 2018). This class of Computable General Equilibrium (CGE) models, however, has a limited treatment of the financial sector and assumes that all resources and factors of production are fully employed, there is no idle capacity and no inter-temporal financial intermediation (Pollitt and Mercure 2018b). Investment cannot assume larger values than the sum of previously determined savings, as a fixed proportion of income. Such constraint, as stressed by Mercure et al. (2019), implies that investment in low-carbon infrastructure, under the equilibrium assumptions, necessarily creates a (neo-Ricardian) crowding-out effect that contracts the remaining sectors. Box 15.6, Figure 1 shows the implications (in the red-shaded part of Figure 1).

Post-Keynesian demand-side macroeconomic models, with financial sectors and supply-side effects, in contrast, allow for the reality of non-equilibrium situations: persistent short- to medium-term underemployed economy-wide resources and excess savings over investment because of unexpected shocks, such as COVID-19. In these settings, economic stimulus packages allow a faster recovery

Box 15.6, Figure 1 | Two worlds – energy transition outcomes under alternative model assumptions (Keynesian vs General Equilibrium).
Source: Mercure et al. (2019).

Box 15.6 (continued)

with demand-led effects: 'Economic multipliers are near zero when the economy operates near capacity. In contrast, during crises such as the GFC, economic multipliers can be high' (Blanchard and Leigh 2013; Hepburn et al. 2020b). The expected results are opposite to the standard supply-led equilibrium models as a response to investment stimulus (the green-shaded part of Box 15.6, Figure 1), as intended by 'green-stimulus' packages such as proposed by the EU (Balint et al. 2016; Mercure et al. 2019).

Even if demand-led models work better in depressions, the question nevertheless is whether the additional public borrowing for such 'green stimulus' can be undertaken by market borrowings given already high public debt levels and recovered in the future from taxes as the economy revives. The results of recent macroeconomic modelling work (Liu et al. 2021) represented by 10 major countries/regions suggests answers. It uses a non-standard macroeconomic framework, with Keynesian features such as financial and labour market rigidities and fiscal and monetary rules (McKibbin and Wilcoxon 2013). First, a global 'green stimulus' of about an average of 0.8% of GDP annually in additional fiscal spending between 2020–30 would be required to accelerate the emissions reduction path required for a 1.5°C transition. Second, such a stimulus would also accelerate the global recovery by boosting GDP growth rates by about 0.6% annually during the critical post-COVID period. Third, the optimal tax policy would be to backload the carbon taxes to later in the macroeconomic cycle, both because this would avoid dampening near-term growth while pre-announced carbon tax plans would incentivise long-term private energy transition investment decisions today and provide neutral borrowing. This macroeconomic modelling path thus replicates the 'green stimulus' impacts expected in theory (Box 15.6, Figure 1). There are also some other additional features of the modelled proposal: (i) fiscal stimulus – needed in the aftermath of the pandemic – can be an opportunity to boost green and resilient public infrastructure; (ii) green research and development 'subsidies' are feasible to boost technological innovations; and (iii) income transfers to lower income groups are necessary to offset negative impacts of rising carbon taxes.

Substantial effects of the COVID-19 pandemic, which is relatively unique in its public health impacts when combined with the consequences of deep economy-wide shocks (economic downturn, public finances, and debt), are expected to last for decades even in the absence of no significant future recurrence. A scenario where the pandemic recurs mildly every year for the foreseeable future further hinders GDP and investment recovery, where growth is unlikely to rebound to previous trajectories, even within OECD economies (McKibbin and Vines 2020) and with worse effects in developing regions. History is strongly supportive: studies on the longevity of pandemics' impacts indicate significant macroeconomic effects persisting for decades, with depressed real rates of return, increased precautionary savings (Jordà et al. 2020), unemployment (Rodríguez-Caballero and Vera-Valdés 2020) and social unrest (Barrett and Chen 2021). The direct effect on emissions is likely to be a small reduction from previous trajectories, but the longer-lasting impacts are more on the macroeconomic-finance side. Pandemic responses have increased sovereign debt across countries in all income bands (IMF 2021e). However, its sharp increase in most developing economies and regions has caused debt distress (Bulow et al. 2021), widening the gap in developing countries' access to capital (Hourcade et al. 2021b). While strong coordinated international recovery strategies with climate-compatible economic stimulus is justified (Barbier 2020; Barbier and Burgess 2020; IMF 2020c; Le Quéré et al. 2021; Pollitt et al. 2021), national recovery packages announced do not show substantial alignment with climate goals (D'Orazio 2021; Hourcade et al. 2021b; Rochedo et al. 2021; Shan et al. 2021). Contradictory post-COVID-19 investments in fossil fuel-based infrastructure may create new carbon lock-ins, which would either hinder climate targets or create stranded assets (Hepburn et al. 2020a; Le Quéré et al. 2021; Shan et al. 2021), whilst deepening global inequalities (Hourcade et al. 2021b).

Considerations on global debt levels and debt sustainability as well as implications for climate finance. The Paris Agreement marked the consensus of the international community that a temperature increase of well below 2°C needs to be achieved and the SR1.5 has demonstrated the economic viability of 1.5°C. However, in terms of increase of supply of, in particular, public finance, often the debate is still driven by the question on affordability, considerations around financial debt sustainability and budgetary constraints against the background of macroeconomic headwinds – even more in the (post-)COVID-19 world (*high confidence*). The level of climate alignment of debt is hardly considered in debt-related regulation and/or debt sustainability agreements like the Maastricht Treaty ceilings (3% of GDP government deficit and 60% of GDP (gross) government debt) not considering economic costs of deferred climate action as well as economic benefits of the transformation.

Robust studies on the economic costs and benefits in the short- to long-term of reaching the LTGG exist for only few countries and/or regions, primarily in the developed world (*high confidence*) (e.g. BCG 2018; McKinsey 2020a). With many studies underpinning the strong economic rationale for high investments in the short-term (e.g., McKinsey 2020a), regional differences are significant highlighting the need for extensive cooperation and solidarity initiatives.

For many developing countries, the focus of debt sustainability discussions is on the negative effect of climate change on the future GDP and the uncertainty with regard to short-term effects of climate change and their economic implications (*high confidence*). With long-term economic impacts of climate change being in the focus of the modelling community, the volatility of GDP in the short term driven

by shocks is more difficult to analyse and requires country-specific deep-dives. IPCC scenario data is often not sufficient to perform such analysis with additional assumptions being needed (Acevedo 2016). For debt sustainability analysis, these more short-term impacts are, however, a crucial driver with transparency being limited to the significance of climate-related revision of estimates. The latter might result in a continued overestimation of future GDP as happened in the past, increasing the vulnerability of highly indebted countries (Guzman 2016; Mallucci 2020). While climate change considerations have already impacted country ratings and debt sustainability assessments (and financing costs), it is unclear whether current GDP forecasts are realistic. The review of the IMF debt sustainability framework leads to a stronger focus on vulnerability rather than only income thresholds when deciding upon eligibility for debt relief and/or concessional resources (Mitchell 2015), which could become a mitigation factor for the challenge described before.

Debt levels globally but particularly in developing and vulnerable countries have significantly increased over the past years with current and expected climate change impacts further burdening debt sustainability (*high confidence*). For low- and middle-income countries, 2018 marked a new peak of debt levels amounting to 51% of GDP; between 2010 and 2018, external debt payments as a percentage of government budget grew by 83% in low- and middle-income countries, from an average of 6.71% in 2010 to an average of 12.56% in 2018 (Fresnillo 2020b). COVID-19 has further reduced the fiscal space of many developing governments and/or increased the likelihood of debt stress. With many vulnerable countries already being burdened with higher financing costs, this limited fiscal space further shrinks their ability to actively steer the required transformation (Buhr et al. 2018). Limited progress in increasing debt transparency remains another burden (Section 15.6.7).

Considering the need for responses to both short-term liquidity issues and long-term fiscal space, current G20/IMF/World Bank debt service suspension initiatives are focused on the liquidity issue rather than underlying problems of more structural nature of many low-income countries (Fresnillo 2020a). In order to ensure fiscal space for climate action in the coming decade, a mix between debt relief, deferrals of liabilities, extended debt levels and sustainable lending practices including new solidarity structures need to be considered in addition to higher levels of bilateral and multilateral lending to reduce dependency on capital markets and to bridge the availability of sustainably structured loans for highly vulnerable and indebted countries. More standardised debt-for-climate swaps, a higher share of GDP-linked bonds or structures ensuring (partial) debt cancellation in case countries are hit by physical climate change impacts/shocks appear possible. The 'hurricane' clause introduced by Grenada, or wider natural disaster clauses provide issuers with an option to defer payments of interest and principal in the event of a qualifying natural disaster and can reduce short-term debt stress (UN Addis Ababa Action Agenda Art. 102) (UN 2015a). A mainstreaming of such clauses has been pushed by various international institutions. The collective action clause might be a good example of a loan/debt term which became market standard. Definition of triggers is likely the most complex challenge in this context.

The use of debt-for-nature and debt-for-climate-swaps is still very limited and not mainstreamed but offers significant potential if used correctly (*high confidence*).

An increasing number of debt-for-climate/nature swaps have been seen in recent years applied primarily in international climate cooperation and in bilateral contexts, however, not (yet) to an extent addressing severe and acute debt crises (Essers et al. 2021; Volz et al. 2021) offering significant potential if used correctly (Warland and Michaelowa 2015). Significant lead times, needs-based structuring, transparency with regard to the additionality of financed climate action, uncertainty with regard to own resource constraints and ODA accountability remain as barriers for a massive scale-up needed to make transactions relevant (Mitchell 2015; Fuller et al. 2018; Essers et al. 2021). At the same time, the limitation of the use of debt-based instruments as a response to climate-related disasters and counter-cyclical loans might be necessary (Griffith-Jones and Tyson 2010).

Ensuring efficient debt restructuring and debt relief in events of extreme shocks and imminent over-indebtedness and sovereign debt default are further crucial elements with a joint responsibility of debtors and creditors (UN 2015a). In this context, the Commonwealth Secretariat flagged that the diversification of the lender portfolio made debt restructuring more difficult with more and more heterogeneous stakeholders being involved (Mitchell 2015) and the UN AAAA raising concerns about non-cooperative creditors and disruption of timely completion of debt restructuring (UN 2015a). This is a side effect of a stronger use of capital markets, which needs to be carefully considered in the context of sovereign bond issuances (Section 15.6.7).

Stranded assets. The debate around stranded assets focuses strongly on the loss of value to financial assets for investors (Section 15.6.1), however, stranded assets and resources in the context of the transition towards a low-emission economy 'are expected to become a major economic burden for states and hence the tax payers' (*high confidence*) (EEAC 2016). Assets include not only financial assets but also infrastructure, equipment, contracts, know-how, jobs as well as stranded resources (Bos and Gupta 2019). Besides financial investors and fiscal budgets, consumers remain vulnerable to stranded investments. Against the background of the frequent simultaneousness of losses occurring for financial investors on the one hand and negative employment effects as well as regional development and fiscal effects on the other hand, negotiations about compensations and public support to compensate for negative effects of phasing out of polluting technologies often remain interlinked and compensation mechanisms and related redistribution effects untransparent.

Recent phase-out deals tend to aim for (partial or full) compensation rather than no relief for losses. In contrast to the line of argument in the tobacco industry, the backward-looking approach and a resulting obligation of compensation by investors in polluting assets can be observed rarely with the forward-looking approach of compensations by future winners for current losers dominating – despite the high level of awareness about carbon externalities and resulting climate change impacts among polluters for many years (van der Ploeg and

Rezai 2020). In particular, transactions in the energy sector show a high level of investor protection also against much needed climate action which is also well illustrated by the share of claims settled in favour of foreign investors under the Energy Charter Treaty and investor-state dispute settlement (Bos and Gupta 2019).

Late government action can delay action and consequently strengthen the magnitude of action needed at a later point in time with implications for employment and economic development in impacted regions requiring higher level of fiscal burden (*high confidence*). This has also been considered in the context of global climate cooperation with prolonged support for polluting infrastructure resulting in heavy lock-in effects and higher economic costs in the long run (Bos and Gupta 2019). Despite a significant share of fossil resources which need to become stranded in developing countries to reach the LTGG, REDD+ remains a singular example for international financial cooperation in the context of compensation for stranded resources.

15.6.4 Climate Risk Pooling and Insurance Approaches

Since 2000, the world has been experiencing significant increase in economic losses and damages from natural disasters and weather perils such as tropical cyclones, earthquakes, flooding and drought. Total global estimate of damage is about USD4210 billion, 2000–2018 (Aon Benfield UCL Hazard Research Centre 2019). The largest portion of this is attributed to tropical cyclones (USD1253 billion), followed by flooding (USD914 billion), earthquakes (USD757 billion) and drought (approximately USD372 billion, or about USD20 billion yr⁻¹ losses) (Aon Benfield UCL Hazard Research Centre 2019). In the period 2017–2018, natural catastrophe losses totalled approximately USD219 billion (Bevere 2019). According to the National Oceanic and Atmospheric Administration, 14 weather and climate disasters cost USD91 billion in 2018 (NOAA NCEI 2019). The European Environment Agency reports that ‘disasters caused by weather and climate-related extremes accounted for some 83% of the monetary losses over the period 1980–2017’ for EU Member States (EU-28) and that ‘weather and climate-related losses amounted to EUR426 billion (at 2017 values)’. For the EEA member countries (EEA-33), the ‘total reported economic losses caused by weather and climate-related extremes’ over the same period amounted to approximately EUR453 billion (EEA 2019). Asia Pacific and Oceania has been particularly impacted by typhoon and flooding (China, India, the Philippines) resulting in economic losses of USD58 billion, 2000–2017, and a combination of flooding, typhoon and drought totalling USD89 billion in 2018 (inclusive of loss by private insurers and government sponsored programmes (Aon Benfield UCL Hazard Research Centre 2019). Based on past historical analysis, a region such as the Caribbean, which has experienced climate-related losses equal to 1% of GDP each year since 1960, is expected to have significant increases in such losses in the future leading to possibly upwards of 8% of projected GDP in 2080 (Commonwealth Secretariat 2016). Similarly, Latin American countries, such as Argentina, El Salvador and Guatemala, experienced severe losses in agriculture totalling about USD6 billion due to drought in 2018 (Aon Benfield UCL Hazard Research Centre 2019). In the African region, where climate is projected to get significantly warmer, continuing severe drought in parts of East Africa, Tropical

Cyclone Idai, had devastating economic impacts for Mozambique, Zimbabwe and Malawi (WMO 2019). According to Munich Re, loss from about 100 significant events in 2018 for Africa are estimated at USD1.4 billion (Munich Re 2019).

While there are questions about the sufficiency of insurance products to address the losses and damages of climate-related disasters, insurance can help to cover immediate needs directly, provide rapid response and transfer financial risk in times of extreme crisis (*high confidence*) (GIZ 2015; Lucas 2015; Schoenmaker and Zachmann 2015; Hermann et al. 2016; Wolfrom and Yokoi-Arai 2016; Kreft and Schäfer 2017; UNESCAP 2017; Matias et al. 2018; UNECA 2018; Broberg and Hovani-Bue 2019; EEA 2019; Martinez-Diaz et al. 2019). Commercial insurability is heavily driven by the predictability of losses and the resulting ability to calculate insurance premium levels properly. Climate change has become a major factor of increasing uncertainty. The previously strong reliance on historic data in calculation of premium levels may be but a starting point given the likely need for upward adjustment due to climate change and potential consequential economic damage. Different risk perceptions between policyholders and insurers will create contrary assessments on premium levels and consequently underinsurance. McKinsey (2020b) also stresses the systemic effect of climate change on insurers’ business models and resulting availability of appropriate insurance products.

The conventional approach to such protective or hedging position has been indemnity and other classical insurance micro-, meso- and macro-level schemes (Hermann et al. 2016). These include micro insurance schemes such as index insurance and weather derivative approaches that cover individuals’ specific needs such as coverage for farm crops. Meso-level insurance schemes, which primarily benefit intermediary institutions, such as NGOs, credit unions, financial institutions and farmer credit entities, seek to reduce losses caused by credit default thereby ‘enhancing investment potential’, whereas macro-level insurance schemes ‘allow both insured and uninsured individuals to be compensated for damages caused by extreme weather events’ (Hermann et al. 2016). These macro-level insurance schemes include catastrophe bonds and weather derivatives and so on, that transfer risk to capital markets (Hermann et al. 2016). Over the last decades, there has been a trend towards weather-index insurance and other parametric insurance products based on predefined pay-out risk pooling instruments. It has gained favour with governments in developing regions such as Africa, the Caribbean and the Pacific because it provides certainty and predictability about funding – financial preparedness – for emergency actions and initial reconstruction and reduces moral hazard. This ‘financial resilience’ is also increasingly appealing to the business sector, particularly micro, small and medium enterprises (MSMEs), in developing countries (MEFIN Network and GI RFPI Asia 2016; Woods 2016; Schaer and Kuruppu 2018).

To date, sovereign parametric climate risk pooling as a way of managing climate risk does not seem to have much traction in developed countries and does not appear to be attractive to

actors in the G20 countries. No G20 members are yet party to any climate risk pooling initiative (Kreft and Schäfer 2017). However, international bilateral donors such as the USAID and the UK Foreign, Commonwealth and Development Office (FCDO, formerly DFID), and the multilateral development banks are all, to different extent, supporters of the various climate risk pooling initiatives now operational in developing countries.

As noted also in IPCC AR5, risk sharing and risk transfer strategies provide 'pre-disaster financing arrangements that shift economic risk from one party to another' (IPCC 2012). Risk pooling among countries and regions is relatively advantageous when compared to conventional insurance because of the effective subsidising of 'affected regions' using revenues from unaffected regions which involve pooling among a large subset of countries (*high confidence*) (Lucas 2015). In general, the premiums are less costly than what an individual country or entity can achieve and disbursement is rapid and there are also fewer transaction costs (Lucas 2015; World Bank 2015). The World Bank argues that the experience with the Pacific Catastrophe Risk Insurance Pilot (PCRIP) and Africa Risk Capacity risk pooling (ARC) show savings of 50% in obtaining insurance cover for pooled risk compared with purchasing comparable coverage individually (Lucas 2015; World Bank 2015; ARC 2016). However, it requires, as noted by UNESCAP, 'extensive coordination across participating countries, and entities' (Lucas 2015).

At the same time, this approach has substantial basis risk (actual losses do not equal financial compensation) (*high confidence*) (Hermann et al. 2016). With parametric insurance, pay-outs are pre-defined and based on risk modelling rather than on-the-ground damage assessment so may be less than, equal to, or greater than the actual damage. It does not cover actual losses and damage and therefore, may be insufficient to meet the cost of rehabilitation and reconstruction. It may also be 'non-viable' or damaging to livelihoods in the long run (UNFCCC 2008; Hellmuth et al. 2009; Hermann et al. 2016). Additionally, if the required threshold is not met, there may be no pay-out, though a country may have experienced substantial damages from a climatic event. This occurred for the Solomon Islands in 2014 which discontinued its insurance with the Pacific Catastrophe Risk Insurance Pilot when neither its Santa Cruz earthquake nor the 2014 flash floods were eligible to receive a pay-out under the terms of the insurance (Lucas 2015).

Increasingly, climate risk insurance schemes are being blended into disaster risk management as part of a comprehensive risk management approach (*high confidence*). The best-known example is the Caribbean Catastrophe Risk Insurance Facility (CCRIF SPC 2018), which involves cooperation among Caribbean states, Japan, Canada, UK and France and international organisations such as the World Bank (UNESCAP 2017). But there are growing platforms of such an approach mainly under the umbrella of the G7's InsuResilience Initiative (Deutsche Klimafinanzierung 2020), including, the Pacific Catastrophe Risk Assessment and Financing Initiative for

the Pacific Islands (PCRAFI), the African Risk Capacity (ARC Agency and its financial affiliate), and the African Risk Capacity Limited (ARC Ltd/ the ARC Group) (ARC 2016) and in the Asian region, the South East Asian Disaster Risk Insurance Facility (SEADRIF) and the ASEAN Disaster Risk Financing and Insurance Program (ADRFI), (SEADRIF 2018; GIZ and World Bank 2019; Martinez-Diaz et al. 2019; Vyas et al. 2019; World Bank 2019a). The group of 20 vulnerable countries (V20) has also developed a Sustainable Insurance Facility (SIF), billed as a technical assistance facility for climate-smart¹⁴ insurance for MSMEs in 48 developing countries as well as potentially to de-risk renewable energy in these countries and regions (ACT Alliance 2020; V20 2020; V20 2021).

However, as noted above, climate risk pooling is not a panacea. There are very obvious and significant challenges. According to Kreft and Schäfer (2017), limitations of insurance schemes include coordination challenges, limited scope, destabilisation due to exit of one or more members as premiums rise and inadequate attention to permanence (Schaeffer et al. 2014). There are also challenges with risk diversification, replication, and scalability (*high confidence*). For example, CCRIF is extending both its membership and diversifying its geographic dimensions into Central America in seeking to lower covariate risk (similar shocks among cohorts such as droughts or floods). Under the SPC portfolio, CCRIF is able to segregate risk across the regions. Risk insurance does not obviate from the need to engage in capacity building to scale-up as well as having process for addressing systemic risk. Currently, risk pools have limited sectoral reach and may cover agriculture but not other important sectors such as fisheries and public utilities. Only recently (July 2019) has CCRIF initiated coverage of fisheries with the development of its Caribbean Oceans and Aquaculture Sustainability Facility (COAST) instrument (CCRIF SPC 2019; ACT Alliance 2020). Historically, risk pool mechanisms, like CCRIF and ARC, only cover a small subset of perils, such as tropical cyclones, earthquakes and excess rainfall but do not include other perils such as drought. Since 2016, ARC has increased its scope to cover drought and in 2019 launched ARC Replica, which not only covers drought but offers premiums and coverage to NGOs and the World Food Programme through the START Network and a pastoral drought product for protecting small farmers and ensuring food security. In some regions and countries, there may also be limited access to reinsurance (Schaeffer et al. 2014; Lucas 2015). An important down-side of climate risk pooling is that it does not cover the actual cost of damage and losses. Though on the positive side, pay-out may exceed costs, but it may also be less than costs. Hence, the parametric approach is not a panacea and does not preclude having recourse to conventional indemnity insurance, which will cover full damage costs after a climate change event as it involves full on-the-ground assessment of factors such as the necessity and costs of repair versus, say, replacement value of damaged infrastructure. This may be important for governmental and publicly provided services such as schools, hospitals, roads, airports, communications equipment and water supply facilities. Given the growing popularity of parametric insurance and climate risk

¹⁴ According to the V20, 'the term "climate-smart" captures the need for two types of climate-related insurance products for MSMEs in vulnerable economies: (1) Climate risk insurance (2) Insurance products which enable low carbon investments, and thereby contribute to increased efficiencies through cost-savings from cheaper low-carbon technologies' (V20 2021).

pooling, there are very ambitious attempts to expand this approach on several fronts (Scherer 2017). Schoenmaker and Zachmann (2015) have proposed a global climate risk pool to help the most vulnerable countries. The pathway to this includes capacity building in underdeveloped financing sectors of developing countries. They argue that as climate extremes become more normalised, they will wipe out significant parts of the infrastructure and productive capacity of developing countries. This will have knock-on impact on fiscal capacity due to lowered tax revenue and high rebuilding costs. 'Developing countries', Schoenmaker and Zachmann (2015) argue, 'cannot insure against such events on a market basis, nor would it be sensible to divert scarce fiscal resources away from infrastructure investment into accumulating a financial buffer for such situations'. In that context, Schoenmaker and Zachmann (2015) call for international risk pooling as 'the only sensible strategy', especially if it addresses the major gaps in climate risk insurance for poor and vulnerable communities by enhancing demand through 'smart support instrument' for premium support such as full or partial premium subsidies and investment in providing risk reduction (Schäfer et al. 2016; Le Quesne et al. 2017; MCII 2018; Vyas et al. 2019). This, it is argued, may help to smoothen out the limited uptake of regional institutions such as ARC and CCRIF SPC, which are only in three regions of the world (with missing mechanism in South America) (Kreft and Schäfer 2017). Existing regional mechanisms, while they may perform very well, only cover a portion of climatic hazards and tend to have limited subscribers. For example, across the key four sovereign risk pools (ARC, CRIFSPC, PCRAFI and SEADRIF), though there are 68 countries only one-third or 32% have purchased coverage in 2019 and 46% 'did not deploy disaster risk financing instruments' (ACT Alliance 2020).

Other gaps and challenges flagged by Kreft and Schäfer (2017) include limited coverage of the full spectrum of contingency risks experienced by countries, inadequate role of risk management as a standard for all regional pools, though there are some emerging best practices in terms of data provision on weather-related risks, and incentivisation of risk reduction (*high confidence*). Here, they recognise the work of Africa Risk Capacity for not only providing the infrastructure to trigger disbursement but for also promoting national risk analysis. Another important gap in the landscape of climate risk pooling is lack of attention to financial institutions' lending portfolios that are vulnerable to weather shocks. In this regard subsidies as part of innovative financing schemes facilitated by the donor community can encourage the uptake of meso-level climate risk insurance solutions (Kreft and Schäfer 2017).

In the literature, there are two attempts at systematic evaluation or comprehensive assessment of regional climate risk pools: a comprehensive study by Scherer (2017) and FCDO's ten-year evaluation (2015–2024). Overall, neither of these studies draw adverse conclusions about regional climate risk pooling initiatives/mechanisms. According to Scherer, 'it appears that insurances work in principle and there is certainly success' and 'initial experiences demonstrate regional climate risk insurances works'. The author cited the 28 pay-outs to 16 countries of USD106 million arguing that it provides cash-starved countries with much needed cash (Scherer 2017, p. 4). The FCDO study (Scott 2017) examines the uptake of

ARC and its impact on reducing vulnerability to disasters. It notes that there is scarce literature on disaster risk insurance mechanisms in terms of impacts. In its current sample of 20 countries as of November 2017, four are projected to experience food security crisis (IPC Level 3) but are not signatories to the ARC, which may signal that ARC is not attractive to all food insecure countries and that there is no overwhelming appetite for ARC among poorer countries. Additionally, Panda and Surminski (2020) research the importance of indicators and frameworks for monitoring the performance and impact of Coalition for Disaster Resilient Infrastructure (CDRI) but make no final assessment of any of the regional climate risk pool. However, they propose mechanisms to improve the transparency and accountability of the system. Scherer (2017), Forest (2018) and Panda and Surminski (2020) seem to indicate that there is 'enthusiasm to support and scale-up regional climate risk insurance' (Scherer 2017, p. 4). Examples of this support include: the Germany Ministry for Economic Cooperation and Development (BMZ) has provided USD5.9 million for the World Food Programme (WFP) to protect 1.2 million vulnerable African farmers with climate risk insurance, through ARC Replica, and the G7 InsuResilience Vision 2025, which has committed to ensuring 400–500 million poor persons are covered against disaster shock by pre-arranged finance and insurance mechanism by 2025; some of this will be through ARC (WFP 2020). Of course, this does not mean that risk pools are without challenges or are not failing on specific sets of metrics. Forest (2018) flags three failing areas: policy holder and hazard coverage, the cost of premium and risk transfer parameters, and the use of pay-out, which in most cases are up to the government. Here, ARC is flagged among the three regional risk pools, as the only one with contingency plan requirements that can support effective use of pay-outs. Other research exploring climate risk pooling and its impacts flag lack of transparency around pay-out, premium or risk transfer parameters. Ultimately, climate risk pools are not full insurance; they offer only limited coverage. Entities such as the U4 Anti-Corruption Help Desk are exploring how to mitigate potential corruption with regard to climate risk insurance.

15.6.5 Widen the Focus of Relevant Actors: Role of Communities, Cities and Subnational Levels

There is an urgency and demand to meet the financial needs of the climate change actions not only at the national level but also at the subnational level, to achieve low-carbon and climate-resilient cities and communities (*high confidence*) (Barnard 2015; Moro et al. 2018). Scaling up subnational climate finance and investment is a necessary condition to achieve climate change mitigation and adaptation action (Ahmad et al. 2019).

The importance of exploring effective subnational climate finance. Stronger subnational climate action is indispensable to adapt cities to build more sustainable, climate-positive communities (Kuramochi et al. 2020). It has transformative potential as a key enabler of inclusive urban economic development through the building of resilient communities (*high confidence*) (Floater et al. 2017a; Colenbrander et al. 2018b; Ahmad et al. 2019). Yet the significant potential of subnational climate finance mechanisms remains unfulfilled. Policy frameworks, governance, and choices at

higher levels underpin subnational climate investments (Colenbrander et al. 2018b; Hadfield and Cook 2019). To scale climate investment, a systematic understanding of the preconditions to mobilising high-potential financing instruments at the national and subnational levels is necessary.

Subnational climate finance needs and flows. Subnational climate finance covers financing mechanisms reaching or utilising subnational actors to develop climate positive investment in urban areas. The fragility of interconnected national and subnational finances affects subnational finance flows, including the impact of the social-economic crisis (Canuto and Liu 2010; Ahrend et al. 2013). The effect of deficit in investment for global infrastructure towards the growing subnational-level debt also creates pressure on subnational finances and constrains future access to financing (*high confidence*) (Smoke 2019).

The International Finance Corporation estimates a cumulative climate investment opportunity of USD29.4 trillion across six urban sectors (waste, renewable energy, public transportation, water, EVs, and green buildings) in emerging market cities, cities in developing countries with more than 500,000 population, to 2030 (IFC 2018). However, the State of Cities Climate Finance report estimated that an average of USD384 billion was invested in urban climate finance annually in 2017–2018 (Negreiros et al. 2021). The International Institute for Environment and Development estimates that out of the USD17.4 billion total investments in climate finance, less than 10% (USD1.5 billion) was approved for locally-focused climate change projects between 2003 and 2016 (Soanes et al. 2017).

Subnational climate public and private finance. Urban climate finance and investment are prominent in the subnational climate finance landscape (CCFLA 2015; Buchner et al. 2019). Finance mechanisms that can support climate investment for the urban sector include public-private partnerships (PPPs); international finance; national investment vehicles; pricing, regulation, standards; land value capture; debt finance; and fiscal decentralisation (Granoff et al. 2016; Floater et al. 2017b; Gorelick 2018; White and Wahba 2019). Among these mechanisms, PPPs, debt finance, and land value capture have the potential to mobilise private finance (Ahmad et al. 2019). Better standardisation in processes is needed, including those bearing on contracts and regulatory arrangement, to reflect local specificities (Bayliss and Van Waeyenberge 2018) (Section 15.6.1.1).

PPPs are particularly important in cities with mature financial systems as the effectiveness of PPPs depends on appropriate investment architecture at scale and government capacity (*high confidence*). Such cities can enable infrastructure such as renewable energy production and distribution, water networks, and building developments to generate consumer revenue streams that incentivise private investors to purchase equity as a long-term investment (Floater et al. 2017b).

National-level investment vehicles can provide leadership for subnational climate financing and crowd in private finance by providing early-stage market support to technologies or evidence related to asset performance and costs-benefits (*high confidence*). The use of carbon pricing is increasing at the subnational level

along with regulation and standards on negative externalities, such as pollution, to steer investment towards climate financing (World Bank Group 2019).

Debt financing via subnational bonds and borrowing, including municipal bonds, is another potential tool for raising upfront capital, especially for rich cities (*high confidence*). The share of subnational, sub-sovereign, and sovereign bonds could grow over time, given efforts to expand the creditworthiness and ensure a sufficient supply of own-source revenue to reduce the default risk. As of now, subnational and sub-sovereign bonds are constrained by public finance limits and the fiscal capacities of governments. However, while green bonds have potential for growth at the subnational level and may result in a lower cost of capital in some cases, the market faces challenges related to scaling up and has been associated with limited measurable environmental impact to date (Section 15.6.8). Further, bonds with lower credit ratings drive higher issuance costs for climate risk cities, for example, costs related to disclosure and reporting (Painter 2020).

Key challenges of subnational climate finance. Across all types of cities, five key challenges constrain the flow of subnational climate finance (*high confidence*): (i) difficulties in mobilising and scaling-up private financing (Granoff et al. 2016); (ii) deficient existing architecture in providing investment on the scale and with the characteristics needed (Anguelovski and Carmin 2011; Brugmann 2012); (iii) political-economic uncertainties, primarily related to innovation and lock-in barriers that increase investment risks (Unruh 2002; Cook and Chu 2018; White and Wahba 2019); (iv) the deficit in investment for global infrastructure affects the growing subnational-level debt (Canuto and Liu 2010); and (v) insufficient positive value capture (Foxon et al. 2015).

Different finance challenges between rich and poor cities. Access to capital markets has been one of the major sources for subnational financing and is generally limited to rich cities, and much of this occurs through loans (*high confidence*). Different challenges to accessing capital markets associated with wealthy and poorer cities are compounded into three main issues: (i) scarcity and access of financial resources (Bahl and Linn 2014; Colenbrander et al. 2018b; Cook and Chu 2018; Gorelick 2018); (ii) the level of implication from the existing distributional uncertainties to the current financing of infrastructural decarbonisation across carbon markets (Silver 2015); and (iii) the policy and jurisdictional ambiguity in urban public finance institutions (Padigala and Kraleti 2014; Cook and Chu 2018). In poorer cities, these differing features continue to be inhibited by contextual characteristics of subnational finance, including gaps in domestic and foreign capital (Meltzer 2016), the mismatch between investment needs and available finance (Gorelick 2018), weak financial autonomy, insufficient financial maturity, investment-grade credit ratings in local debt markets (Bahl and Linn 2014), scarce diversified funding sources and stakeholders (Gorelick 2018; Zhan et al. 2018; Zhan and de Jong 2018) and weak enabling environments (Granoff et al. 2016).

The depth and character of the local capital market also affect cities differently in generating bonds (*high confidence*). Challenges

facing cities in developing countries include insufficient appropriate institutional arrangements, the issues of minimum size, and high transaction costs associated with green bonds (Banga 2019). Green projects and project pipelines are generally smaller in scale feasible for a bond market transaction (Saha and D'Almeida 2017; DFID 2020). De-risking in the different phases of long-term project financing can be promoted to improve the appetite of capital markets (Section in 15.6.7).

Climate investment and finance for communities. There is insufficient evidence about which financing schemes contribute to climate change mitigation and adaptations at community level (*high confidence*). There is growing interest in the linkages between microfinance and adaptation in the agriculture sector (Agrawala and Carraro 2010; Fenton et al. 2015; Chirambo 2016; CIF 2018; Dowla 2018), the finance for community-based adaptation actions (Fenton et al. 2014; Sharma et al. 2014), and the relations between remittances and adaptation (Le De et al. 2013). However, there is less discussion on community finance aside from the benefits of community finance and village funds in contributing to close investment gaps and community-based mitigation in the renewable energy and forest sectors (Ebers Broughel and Hampl 2018; Bauwens 2019; Watts et al. 2019). The full potential and barriers of the community finance model are still unknown and research needs to expand understanding of favourable policy environments for community finance (Bauwens 2019; Watts et al. 2019).

Implications for the transformation pathway. Cities often have capacity constraints on planning and preparing capital investment plans. Integrated urban capital investment planning is an option to develop cross-sectoral solutions that reduce investment needs, boost coordination capacity, and increase climate-smart impacts (*high confidence*) (Negreiros et al. 2021). In countries with weak and poorly functioning intergovernmental systems, alliances and networks may influence their organisational ability to translate adaptive capacity for transformation into actions (Leck and Roberts 2015; Colenbrander et al. 2018a). Deepening understanding of country-specific enabling environment for mobilising urban climate finance among and within cities and communities, design of policy, institutional practices and intergovernmental systems are needed to reduce negative implications of transformation (Steele et al. 2015).

15.6.6 Innovative Financial Products

Innovative financial products with increased transparency on climate risk have attracted investor demand, and can facilitate investor identification of low-carbon investments (*high confidence*). Innovative products may not necessarily increase financial flows for climate solutions in the near term, however they can help build capacity on climate risk and opportunities within institutions and companies to pave the way for increased flows over time.

Investor demand is driving developments in innovative financial products (*high confidence*). Since AR5, innovative financial products such as sustainability and green-labelled financial products have proliferated (Section 15.3). These financial products

are not necessarily 'new' in terms of financial design but are packaged or labelled in an innovative way to attract responsible and impact-oriented institutional investors.

The growth and diversity of the green bond market illustrates how innovative financial products can attract both public and private investors (*high confidence*). Demand for green financial products initially stemmed from public sector pension funds. Pension funds and insurance companies in OECD countries have traditionally favoured bonds as an asset class with lower risk (OECD and Bloomberg 2015).

Since AR5, labelled green bonds have grown significantly, exceeding USD290 billion issued in 2020 with a total of USD1.1 trillion in outstanding bonds (CBI 2021a) (Section 15.6.7). Corporates, financial institutions and government-backed entities (for example in real estate, retail, manufacturing, energy utilities) issued the largest volumes, with use of proceeds focused primarily on GHG mitigation in energy, buildings and transport projects (CBI 2021a). Given their focus on GHG mitigation, green bonds are also sometimes referred to as climate bonds, but the common market terminology is 'green'. Municipal green bond issuance has also been growing (Section 15.6.7). Beyond green bonds, additional products such as green loans, green commercial paper, green initial public offerings (IPOs), green commodities, and sustainability-linked bonds and loans have also been introduced in the market (CBI 2019a) (Section 15.6.7).

Investor demand for green bonds is evidenced by over-subscription of deals. Recent studies indicate an over-subscription for green-labelled bonds by an average of between three and five times, as compared to non-labelled bonds (Gore and Berrospi 2019; Nauman 2020). Results of a survey of global treasurers showed a higher demand for green bonds than non-labelled bonds for 70% of the respondents (CBI 2020a).

The financial crisis associated with COVID-19 has put increased pressure on debt issuers, and the extent to which the increase in indebtedness for sovereigns and corporates has been financed via climate-related-labelled debt products is not known. Further, at this time there is no identified literature assessing the degree to which international versus domestic investors are financing sovereign green debt in developing countries (Section 15.6.7). However, since the onset of the COVID-19 crisis, continued steady growth in issuance has been observed broadly across sustainable bonds (including green, social and sustainability bonds), with more significant growth in social bonds to support the COVID-19 recovery (Maltais and Nykvist 2020; CBI 2021a).

Index providers and exchanges can also play a supporting role in transparency for identification of benchmarks and innovative financial products for climate action. Low-carbon indices have proliferated in recent years, with varying approaches including reduced exposure to fossil, best-in-class performers within a sector, and fossil-free (UN PRI 2018) (see discussion on ESG index performance that follows in this section). Indices can provide transparency on low-carbon opportunities, making it simpler for funds and investors to identify green investment options. Exchanges can also play a supporting role to the uptake of green financial products through transparent

listings and requirements to improve credibility of green labelling. The number of green or sustainability bond listing segments tripled from five in 2016 to 15 in 2018 (SSE 2018). Green security listings can also be used to enhance local capital markets (Section 15.6.7).

Significant potential exists for continued growth in innovative financial products, though some challenges remain (*high confidence*). Despite recent growth and diversification, green bonds face several challenges in scaling up. Issuance of green-labelled bonds constitutes approximately 1% of the global bond market issuance (ICMA 2020b; CBI 2021a). Potential exists to increase issuance amongst corporates, for instance, and across a broader regional scope (although subject to limitations of local capital markets). Yet there remain several challenges to growing the green bond market, including *inter alia* concerns about greenwashing and limitations in application to developing countries (Shishlov et al. 2018; Banga 2019).

There is no globally accepted definition of green bonds, and varied definitions of eligible green activities are evolving across regional bond markets. Beyond the most commonly used green label, other related labels such as blue, sustainable, transition, sustainable development goal (SDG), social and environmental, social and governance (ESG) have some overlapping applications (Schumacher 2020). The degree to which these labels represent climate-relevant investments depends on underlying criteria and how they are applied (Section 15.6.4).

There are several initiatives aimed at protecting the integrity of the green label. Guidance on use and management of proceeds established by the International Capital Markets Association's Green Bond Principles (GBP) is followed on a voluntary basis, which notes eligible use of proceeds as primarily climate mitigation and adaptation projects. The GBP also recommend independent external reviews at the time of issuance, with 89% of green bond issuers in 2020 having external reviews at the time of issuance (CBI 2021a). In addition to best practice based on voluntary principles, a further check on greenwashing, although insufficient on its own, is the fear of reputation risk on behalf of investors, issuers and intermediaries in the age of social media (Hoepner et al. 2017; Deschryver and de Mariz 2020). A report on post-issuance green bond impact reporting notes that despite concerns (Shishlov et al. 2018), greenwashing incidence is rare, with 77% of green bond issuers reporting on allocation and 59% reporting on impact, but with significant variance in quality and consistency of impact reporting (CBI 2021b).

Financial disclosure regulatory developments can help further align and specify definitions of green in the financial sector but are not a substitute for climate policy (*high confidence*). Developing a common basis for understanding a green label could further reduce uncertainty or concerns of greenwashing. Regulatory developments in some regions seek to further guard against greenwashing with more specific definitions. The EU sustainable finance package, including the EU Taxonomy and EU Green Bond Standard draft regulations, is the broadest reaching, but not the only, regional initiative focused on disclosure of climate risk (Section 15.6.3). Taxonomies across regions are not always aligned on what can constitute a green project,

for example with respect to transition activities (Pfaff et al. 2021) (Section 15.6.7). While standardisation can help reduce uncertainty in markets with imperfect knowledge, the green bond market is currently developing and is expected to continue to reflect regional differences in economic governance approaches (Nedopil et al. 2021). Regulations may also have trade-offs in terms of transaction costs for green financial product issuers. Classification approaches can also face challenges, depending on how they are designed, in their ability to capture new technologies and social impacts (Section 15.4).

Green bonds have been primarily targeting climate mitigation projects, with far fewer projects identified as adaptation. Green bonds mainly finance projects in the energy, buildings and transportation sectors, which constituted 85% of the use of proceeds of green bonds in 2020 (CBI 2020b, 2021a). Agriculture and forestry projects, including adaptation projects, have been less suited to be financed in a bond structure, which could be in part due to the more dispersed and smaller nature of the projects and in part due to project 'bankability' or ability to contribute steady streams of financing to pay back the terms of a bond. However, adaptation projects may not be identified as such as resiliency becomes more mainstreamed into infrastructure planning (Section 15.3.2).

While green bonds have the potential to further support financial flows to developing countries, local capital markets can be at varying stages of development (Banga 2019) (Sections 15.6.2 and 15.6.7). While multilateral and bilateral development finance institutions have been active in the green bond market, global issuance in 2020 in the top 10 countries included only one developing country (CBI 2021a). Targeting international investors can be enhanced via de-risking activities (15.6.4).

Identifying green financial products can increase uptake and may result in a lower cost of capital in certain parts of the market (*high confidence*). Investors face a systematic underpricing of climate risk in financial markets (Krogstrup and Oman 2019; Kumar et al. 2019). Transparent identification of financial products can make it easier for investors to include low-carbon products in their portfolios. Investors with mandates that include or are focused on climate change are showing an interest in green-labelled financial products. Investors that identify themselves as green constitute approximately 53% of the investor base for green bonds in the first half of 2019 (CBI 2019b).

There is some evidence of a premium, or an acceptance of lower yields by the investor, for green bonds (*medium confidence*). A survey of recent literature finds some consensus of the existence of a green premium in 56% of the studies on the primary markets (with a wide variance of premium amount), and 70% of the studies on the secondary market (with an average premium of -1 to -9 basis points), particularly for government issued, investment grade and green bonds that follow defined governance and reporting practices (MacAskill et al. 2021). In the US municipal bond market, as credit quality for green-labelled bonds has increased in the past few years, some studies show a positive premium for green bonds is arising (Baker et al. 2018; Karpf and Mandel 2018), or appearing only in the secondary market (Partridge and Medda 2020), while others

find no evidence of a premium (Hyun et al. 2019; Larcker and Watts 2020). Several studies also show a recent emergence of a premium and oversubscription for some green-labelled bonds denominated in EUR (CBI 2019b), in some cases for both USD or EUR green bonds (Ehlers and Packer 2017), with a wide variation in the range of the observed difference in basis points focusing on the secondary market (Gianfrate and Peri 2019; Nanayakkara and Colombage 2019; Zerbib 2019), with financial institution and corporate green bonds exhibiting a marginal premium compared with their non-green comparisons (Hachenberg and Schiereck 2018; Kempa et al. 2021).

Spillover effects of green bonds may also impact equity markets and other financing conditions. Stock prices have been shown to positively respond to green bond issuance (Tang and Zhang 2020). One study linked enhanced credit quality induced by issuing green-labelled bonds to a lower cost of capital for corporate issuers (Agliardi and Agliardi 2019). Issuers' reputation and use of third-party verification can also improve financing conditions for green bonds (Bachelet et al. 2019). Green bonds are strongly dependent on fixed income market movements and are impacted by significant price spillover from the corporate and treasury bond markets (Reboredo 2018). A simulation of future green sovereign bond issuances shows that this can promote green finance via firm's expectations and the credit market (Monasterolo and Raberto 2018).

Financial flows via these instruments have limited measurable environmental impact to date, however they can support capacity building on climate risk and opportunities within institutions to realise future impacts (*high confidence*). There is a lack of evidence to date that green and sustainable financial products have significant impacts in terms of climate change mitigation and adaptation (Box 15.7). Further, new products must be coupled with tightened climate policy and a reduction in investments associated with GHG-emitting activities to make a difference on the climate (Section 15.3.3.2).

It is challenging to link specific emission reductions with specific instruments that mainly target climate activities such as green bonds.

Data challenges point to an inability to link emission reductions, including Scope 3 GHG emissions, at the organisation or firm level with green bond use-of-proceeds issuance (Ehlers et al. 2020; Tuhkanen and Vulturius 2020). However one study found evidence of a signalling effect of issuing green bonds resulting in emission reductions at the corporate level following issuance (Flammer 2020), and another study characterised the lifecycle emissions of renewable energy financed by green bonds, indicating potentially substantive avoided emissions but with variance up to a factor of 12 across bonds depending on underlying assumptions (Gibon et al. 2020). There is also a lack of impact reporting requirements and consistency in the green bond market. Impact reporting is not typically required for green bond listings on specific exchanges, nor are there any requirements for independent reviews of impact reporting, however this could change in future if investors apply pressure.

Green-labelled products may not necessarily result in increased financial flows to climate projects, although there can be benefits from capacity building with issuing institutions. Green bonds can be used to finance new climate projects or refinance existing climate projects, and thus do not necessarily result in finance for new climate projects constituting additional GHG reductions (a framing used in the Clean Development Mechanism). The labelling process itself may not necessarily lead to additional financing (Dupre et al. 2018; Nicol et al. 2018b). However, the labelling process has merit in contributing to building capacity within issuing institutions on climate change (Schneeweiss 2019), which could support identification of new green projects in the pipeline.

Climate risk disclosure initiatives, some of which are voluntary in nature, may have a limited direct climate impact. Transparency on climate risk may not change investor decisions nor result in divestment, especially in the emerging economies, as support and clear direction from regulatory and policy mechanisms are required to drive institutional investors at large (Ameli et al. 2021b). On the other hand, there is evidence of reduced fossil fuel investments following mandatory climate risk disclosure requirements, indicating a broader signalling effect of transparency (Mésonnier and Nguyen 2021).

Box 15.7 | Impact of ESG and Sustainable Finance Products and Strategies

While scaling up climate finance remains a challenge (Section 15.3.2), there is consensus that investments that are managed taking into account broader sustainability criteria have increased consistently and ESG integration into sustainable investment is increasingly being mainstreamed by the financial sector over recent years (Maiti 2021). The United Nations Principles for Responsible Investment (PRI) grew to over 3000 signatories in 2020, representing over USD100 trillion in assets under management (UN PRI 2020). And according to the 2018 biennial assessment by Global Sustainable Investment Alliance,¹⁵ sustainable investments in five major developed economies grew by 34% in the two-year period following the 2016 assessment. The primary ESG approaches leveraged were exclusion criteria and ESG integration, which together amounted to over USD37 trillion, accounting for two-thirds of the assessed sustainable investments, with novel strategies such as best-in class screening and sustainability-themed investing showing significant growth, although together they accounted for around 6% of these investments (GSIA 2019). Shareholder activism or corporate engagement is the other key approach, which has been well established and continued to grow to nearly USD10 trillion (GSIA 2019).

¹⁵ GSIA is an international collaboration of membership-based sustainable investment organisations.

Box 15.7 (continued)

However, research indicates that ESG strategies by themselves do not yield meaningful social or environmental outcomes (Kölbel et al. 2020). When it comes to the tangible impact of the financial sector on addressing climate change and sustainable development, there remains ambiguity. There is a growing need for more robust assessment of ESG scores, including establishing higher standardisation of scoring processes and a common understanding of the different ESG criteria and their tangible impact on addressing climate change. The issue was highlighted in an assessment of six of the leading ESG rating agencies' company ratings under the MIT Aggregate Confusion Project, which found the correlation among them to be 0.61, leading them to conclude that available ESG data was 'noisy and unreliable' (Berg et al. 2020). This need is reaffirmed by Drempetic et al. (2020), who claim that a thorough investigation of ESG scores remains a relatively neglected topic, with extraneous factors, such as firm size, influencing the score (Drempetic et al. 2020).

There continues to be a research gap in assessing the direct impact of ESG and sustainable investments on climate change indicators, with most existing studies assessing the co-relation between either the factors driving the sustainable finance trends and the impact on sustainable investments, or sustainable investments and the impact on corporate financial performance. Nevertheless, since the post-SDG adoption period, there has been a notable uptake on research linking sustainable business practices and financial performance (Muhmad and Muhamad 2020). This research shows that there is a growing business case for ESG investing, with evidence increasingly indicating a non-negative co-relation between ESG, SDG adoption and corporate financial performance (Friede et al. 2015; Muhmad and Muhamad 2020), and ESG performance having a positive relation with stock returns (Consolandi et al. 2020). Research focused on developed economies also indicates towards a positive relation between ESG criteria and disclosure, and economic sustainability of a firm (Giese et al. 2019; Alsayegh et al. 2020) and allays investor fears by showing that sustainable finance initiatives, such as divestment, do not adversely impact investment portfolio performance (Henriques and Sadorsky 2018; Trinks et al. 2018). It should be reiterated that this research assesses the co-relation between ESG criteria and corporate financial performance, with the researchers in some cases, such as Friede et al. (2015), including disclaimers of the results being inconclusive and highlighting the need for a deeper assessment for linking ESG criteria with impact on financial performance.

On the other hand, there is growing evidence for a sustainable investment lens having a broader positive impact on creating an enabling environment and strengthening the case for such investments. For instance, corporate social responsibility (CSR) activities and investments on the environment dimension, specifically in the areas of emission and resource reduction, were found to be profitable and a predictor of future abnormal returns in the longer term, from additional cash flow and additional demand (Dorflleitner et al. 2018). These factors could be contributing to the increasing trend of sustainable and green investments, and can be said to be further reiterated by the spate of investor-led collaborative initiatives and recent announcements by leading finance institutes in the developed economies, which is well recorded in a range of recent grey literature, including new climate-aligned investment strategies and ambition towards net zero targets.

Yet there is also a risk of companies announcing projected sustainability or net zero targets and claiming the associated positive reputational impact, while having no clear action plan in place to achieve these. The lack of mandatory reporting frameworks, which results in an over-reliance on self-reported carbon data by companies for ESG assessments, can be a primary contributor (In and Schumacher 2021).

While there is a lack of research on the impact of sustainable finance products, divestment impact has been assessed in more detail. Although the research here also points towards the ambiguous direct impact of divestment on reducing GHG emissions or on the financial performance of fossil fuel companies, its indirect impact on framing the narrative around sustainable finance decisions (Bergman 2018), and the inherent potential of the divestment movement for building awareness and mobilising broader public support for effective climate policies, have been better researched and could be considered to be the more relevant outcomes (Braungardt et al. 2019). Arguments against divestment point to its largely symbolic nature, but Braungardt et al. (2019) elaborate on the broader positive impacts of divestment, which include its ability to spur climate action as a moral imperative and stigmatise and reduce the power of the fossil fuel lobby, and the potential of the approach to mitigate systemic financial risks arising due to climate change and address the legal responsibilities of investors merging in this regard.

Challenges remain with regards to overlapping definitions of sustainable and ESG investment opportunities, which also vary depending on social norms and pathways. There is also a general need for more extensive ESG disclosure at a corporate level, against the background of emerging mandatory impact reporting for asset managers in some regions. A movement is building towards sustainable investment strategies and increased sustainable development awareness in the financial sector (Muhmad and Muhamad 2020; Maiti 2021), which points to the ability of civil society movements, such as divestment campaigns, to have some influence on investor behaviour, although there are other influences such as climate risk disclosure initiatives and regulations.

15.6.7 Development of Local Capital Markets

International situational context. Developing countries make up two-thirds of the world's population and carry carbon-intensive economies where 70% of investments (see Chapter 3) need to be conducted to limit warming to 2°C. The focus for climate investments has been on China, USA, Europe, India and the G20 (UNEP 2019) but studies highlight Paris and SDG attention should be devoted to Africa, LDCs and SIDS (African Union Commission 2015; Feindouno et al. 2020; GCA-AAI 2020; Warner 2020; AOSIS 2021). The 'special needs, circumstances and vulnerability' of African, LDC and SIDS nations are recognised under UNFCCC and UN agreements (UN 2009, 2015a,b,c; UNFCCC 2010, 2015; Pauw et al. 2019). These nations currently contribute very little to global emissions. Developing countries with their growing economies, including the vast African continent roughly the size of China, Europe, USA, and India combined (IEA 2014b, p. 20) with a 1 billion population expected to double by 2050, growing reliance on fossil fuels and 'cheap' biomass (charcoal use and deforestation) amid rising urbanisation and industrialisation ambitions – collectively these nations hold large leap-frog potential for the energy transition as well as risks of infrastructure lock-in. Accelerated international cooperation is a critical enabler (IPCC 2018) in recognising this potential. This could mobilise global savings, scale up development of local capital markets for accelerated low-carbon investment and adaptation in low- and lower-middle-income countries as well as tackle illicit finance including tax avoidance leakages that deprive developing countries of valuable resources (US DoJ 2009; Hearson 2014; Hanlon 2017; US DoJ 2019; IATFD 2021). Diversifying funding sources is important at a time hard-currency Eurobond issuances reach records (Panizza and Taddei 2020; Moody's Investors Service 2021). Otherwise, the structure of voluntary, nationally oriented, and financially fragmented arrangements under the Paris Agreement (Chapter 17) could lead to 'regional rivalry' (SSP 3) pathways (IPCC 2018; Gazzotti et al. 2021). The benefits are many times greater than apparent costs in terms of expected decline in global GHG emissions and attaining SDGs. These could even generate large 'win-win' opportunities back in capital source countries which will benefit from a flow back in import demand (Hourcade et al. 2021a).

Lessons from literature on policy options in mobilising capital for Paris and SDGs in developing countries can be summarised as follows:

1. development of national just transition strategies meet the USD100 billion commitment on a grant-equivalent basis to support NDCs that integrate policies on COVID-19 recovery, climate action, sustainable development and equity;
2. increase the leverage of public funds on diverse sources of private capital through de-risking investments and public-private partnerships involving location-based entities with AAA-rated players and institutional investors;
3. coordination of project preparation and development of project pipelines by infrastructure coordinator agencies, one-stop structuring and financing shops, project risk facilities provided by entities such as cities' development banks, green banks, a world climate bank, global guarantee mechanism, and global infrastructure investment platform;
4. development of local currency bond markets backed by cross-border guarantees, technical assistance, remediation assets, especially by regional and national players whose mandates include nurturing local capital markets to support bond yield curve development and exchange listing options;
5. adopting advances in science-based assessment methods to foster accountability;
 - (a) for project assessment, measuring, reporting and verifying, and certification,
 - (b) for disclosures in climate, fossil fuels, SDGs, debt transparency and debt sustainability, and
 - (c) for progress on UN systems of national accounts particularly for public sector finance statistics.

Whole-of-society approach to mobilising diverse capital. There's no shortage of money globally: it is simply that it has yet to travel to where it's most needed. One challenge is unlocking unencumbered endowments to contribute to Paris and SDGs (*high confidence*). The aggregate global wealth figures exceed USD200 trillion (Davies et al. 2016; UBS 2017; Credit Suisse 2020; Heredia et al. 2020). Some developing countries have run pilots for investing in government bonds capitalising on fintech growth discussed (The Economist 2017; Akwagyiram and Ohuocha 2021) (Section 15.6.6). Others are developing green products to encourage uptake by middle class retail investors (Eurosif 2018; UK DMO 2021). Millennial-aged inheritors expected to receive intergenerational transfers mobilised by global citizen activism (Chapter 2) invest in green retail and tech products (Morgan Stanley 2017; UBS 2017; Capgemini 2021). Historic inequity and diaspora-related private and public resources pledged and debated during the COVID-19 pandemic might have potential to contribute towards Paris and SDGs (Olusoga 2015; Glueck and Friedman 2020; Hall 2020; Piketty 2020; Timsit 2020; Goldman Sachs 2021; Guthrie 2021; Mieu 2021; Wagner 2021). Philanthropic institutions use grants, debt, equity, guarantees and issue investment grade bonds in using unencumbered endowments (Manilla 2018; Covington 2020; Moody's Investors Service 2020) but only about 2% of their resources are dedicated to climate action (Williams T., 2015; Kramer 2017; Morena 2018; Delanoë et al. 2021). The pandemic exemplified the unprecedented collaboration and mobilisation of multilateral and scientific communities supported by the COVAX risk sharing mechanism for COVID-19 vaccines with pooling of financial and scientific resources (OECD 2021d). This momentum in international cooperation can be harnessed to galvanise resources, including for teaching of sciences in developing countries important in tackling society challenges, alleviating poverty (TWAS 2021) and inequity legacies compounded by climate impacts debated by many (Henochsberg 2016; Obregon 2018; Fernandez et al. 2021; The Economist 2021). Suggestions towards equitable models include 'global adaptation funding approaches' (Chancel and Piketty 2015), a 'world climate bank' to finance climate investments through long-term bonds (Foley 2009; Broome 2012; Broome and Foley 2016), a 'cities development bank' (Alexander et al. 2019), and 'public debt financing models' (Rendall 2021) for generations to share the burden which has precedence in history (Draper 2007; Fowler 2015).

Local financial institutions with local markets knowledge could benefit from technical assistance and partnership to scale up their potential with institutional investors better mobilised (high confidence). The Global South has some 260 public development banks/PDBs representing USD5 trillion in assets with a worldwide PDB capacity to provide more than USD400 billion yr⁻¹ of climate finance (IDFC and GCF 2020). Case studies discuss the potential for diaspora bond issuance being deployed for climate investments including securitisation of remittances as collateral for infrastructure bonds (Ketkar and Ratha 2010; Akkoyunlu and Stern 2012; Gelb et al. 2021). Such instruments could help harness diaspora remittances, whose flows rose from under USD 100 billion to USD530 billion during 1990–2018 (World Bank 2019c). PDBs could benefit from technical partnership with multilaterals and other local banks (Torres and Zeidan 2016). Their knowledge of local markets, can help build project pipelines (Figure 15.7) to channel local, domestic and international capital (Griffith-Jones et al. 2020). Institutional domestic and international investors have growing assets estimated to exceed USD100 trillion (*high confidence*) (Willis Towers Watson 2020; UN PRI 2020; Halland et al. 2021; Heredia et al. 2021; Inderst 2021) and could be better mobilised. Some 36% of total assets under management (AUM) by the 100 largest asset owners come from pensions and sovereign wealth funds in the Asia Pacific region, with the remainder split almost evenly across Europe, the Middle East, Africa and North America. The largest pension fund in South Africa held about USD130 billion AUM in 2019 and African institutional investors held USD1.8 trillion in 2020 (PwC 2015; GEPI 2019; Bagus et al. 2020; GCA 2021a). UK NGO War on Want's (2016) analysis of 101 fossil fuel and mining companies on the London Stock Exchange estimates these as holding USD1 trillion assets inside Africa. The Latin America and Caribbean region holds just about USD1 trillion AUM (Curtis 2016; Serebrisky et al. 2015; Cavallo and Powell 2019).

Investors with accumulated private capital are reported as looking for climate investments to ensure Just Transition, alignment with Paris and SDGs. However, progress remains pilot, slow and piecemeal (high confidence). Global investors have published statements on their possible contribution, with recommendations to governments on de-risking to accelerate private sector investment to support Paris-aligned NDCs in developing countries (IIGCC 2015; IIGCC 2017; Global Investor Statement 2018; IIGCC 2018; Global Investor Statement 2019; IIGCC 2020). In March 2020, the UN Principles for Responsible Investment (PRI), had 3038 members representing USD103 trillion (UN PRI 2020); another coalition of investors published COVID-19 recovery plans (Investor Agenda 2020) and the Net Zero Asset Managers initiative was launched in December 2020 (NZAM 2020). However, it is still unclear how these pronouncements will be transformed to adequate financial flows and volumes of investment pipelines (IEA 2021d) (Chapter 3). Rempel and Gupta (2020) posit that a proportion of institutional holding is in fossil fuels. Clean energy transition minerals raise ESG questions around inclusive development for indigenous populations and require changes to supply chains exploiting child labour (Herrington 2021; IEA 2021a; IEA 2021f).

Options to mobilise institutional investors currently remain small pilots, relative to Paris and SDG ambitions (*high confidence*). In terms

of examples: in the *women of colour-led arena*, a Chicago pension fund invested in a developing country using a *private equity fund*; (Langhorne 2021, USAID 2021). Institutional BlackRock's blended finance vehicle with OECD MDB partners focuses on developing countries (BlackRock 2021). In regional AAA MDB partnerships, the African Development Bank (AfDB) collaborates with African nations through a *regional infrastructure fund* (Africa50 2019); the Asian Development Bank (ADB) collaborates with a Philippines state-owned pension fund and Dutch pension fund in using a *private equity fund* to catalyse private sector investment (ADB 2012). A UN entity with several pooled public-private investment platforms includes an SDG blended finance vehicle (UN CDF 2020a; 2020b). A multilateral International Finance Corporation (IFC) blended finance fund, supported by a sovereign guarantee from Sweden's SIDA, and separately a USD1 billion green bond fund by IFC and Europe's Amundi asset manager buy green securities issued by developing country banks financing local currency climate investments (IFC 2018, 2021; Amundi and IFC 2019). The key parameter is the *investment multiplier*, the *ratio of private investment mobilised by a given amount of public funds* which varies by product type. IFC's portfolio of blended finance investments point to a self-reported range of 3 to 15 times for project debt and even higher levels (10 to 30) for debt finance provided on concessional terms (IFC 2021a). Although an AAA-rated IFC blended finance fund was established in 2013, most investors joined in 2017 with insurers AXA and Swiss Re investing USD500 million each to bring the fund to USD7 billion raised from eight global investors (Attridge and Gouett 2021). Critics of blended finance mechanisms point to lack of data transparency hampering independent assessment on (i) value for public money and costs of blending versus other financial mechanisms, (ii) risks and benefits of de-risking private capital to collateralising climate-vulnerable Global South populations, (iii) lack of partnership with local players, and (iv) complex structures (Akyüz 2017; Mawdsley 2018; Convergence 2020; Attridge and Gouett 2021; Gabor 2021). Whilst blended finance transactions (BFTF 2018) are quite common in mature regulated markets with mandatory reporting requirements (Morse 2015; ICAEW 2021), the additional finance mobilised and their developmental impact remain unknown due to poor reporting that hampers evidence-based policy making (Attridge and Gouett 2021). Projects that are aligned with blended finance principles in the UN Addis Agenda (UN 2015a), and take account of local contexts by partnering with local actors, are much more likely to have sustainable impacts.

De-risking tools to lower capital costs and mobilise diverse investors. Paris-aligned NDCs that integrate policies on COVID-19 pandemic recovery, climate action, sustainable development, just transition and equity can harness co-benefits including contribution to *Invisible UN SDG 7 energy poverty sectors (high confidence)*. Developing countries require access to affordable finance for projects ranging from clean cooking solutions (Accenture 2018; World Bank et al. 2021); decentralised energy systems, intra-country power stations and regionally shared power pools with their associated energy distribution networks (IEA 2020d; IRENA 2020c). Close to 3 billion people in Africa and developing Asia have no access to clean cooking. For sub-Saharan Africa, the acute lack of electricity access lags behind all regions on SDG 7 indicators, impacting mostly

women and children (IEA 2014b; IRENA 2020b,c; IEA et al. 2021; ESMAP 2020; Zhang 2021) (Box 6.1). These dire statistics remind of compounding tensions: historical inequities and the associated ‘first comer’ exploiting African resources for development elsewhere, the local climate change, ‘latecomer’ capacity development and technology transfer challenges, illicit mining finance and stranded assets (Curtis 2016; Bos and Gupta 2019; UNU-INRA 2019; Arezki 2021). The COVID-19 pandemic exacerbates this tension with more people pushed below the poverty line (Sumner et al. 2020) (section 15.6.4, Box 15.6 on post-COVID). Recent analysis points to the 60 largest banks providing USD3.8 trillion to fossil fuel companies since 2016, including inside Africa (Rainforest Action Network et al. 2021). IMF estimated fossil fuel subsidies totalling USD5.2 trillion or 6.5% of global GDP in 2017 (Coady et al. 2019) to be compared with the USD2.4 trillion yr^{-1} energy investments over the next decade to limit global warming to 1.5°C (IPCC 2018). Analysts point to models in improvements to resources husbandry that include (i) developing strong minerals sector governance through sovereign wealth funds for domestic development (Wills et al. 2016) and (ii) compensation for Africa (Walsh et al. 2021) leaving fossil fuels underground (McGlade and Ekins 2015) in the *Just Transition* (Section 15.2.4) and *Right to Develop* debates as assets continue to be mined (IEA 2019c). In many developing regions, some of the world’s best renewable energy sources remain out of reach due to high costs which can be up to seven times those in developed countries (IEA 2021d). Shifting some risks through financial de-risking approaches could be instrumental

(Schmidt 2014; Sweerts et al. 2019; Drumheller et al. 2020; Matthäus and Mehling 2020).

Combining approaches: (i) developed countries meeting UNFCCC USD100 billion commitment on a grant-equivalent basis, (ii) stepped up technical assistance, (iii) infrastructure coordination, (iv) knowledge sharing by project preparation entities, and (v) harnessing project risk facilities such as guarantees could be instrumental for scaling climate finance for Paris-SDGs (*high confidence*). Figure 15.7 illustrates the interplay between infrastructure project financing phases, bond refinancing and opportunities for developing bond yield curve benchmarks in nurturing local capital markets and mobilising diverse investors. These project financing phases have varying risk-return profiles and different benchmarks to track performance are often required by investors for different securities that might be created (Ketterer and Powell 2018).

An ODI (2018) survey of private and public project preparation facilities internationally showed high failure rates in *early project preparation phases* with recommendations on ‘one-stop-shops’ and knowledge sharing on effective approaches. During the very high-risk *concept phase* (Figure 15.7) – grants and technical assistance de-risk with design concepts, project proposals and feasibility studies completed to ‘kick-start’ the right projects. The early-stage developmental phase is characterised by short-term debt in the two to five years phase to

Figure 15.7 | Bond refinancing mobilises institutional investors in mature project phase. De-risk early-stage infrastructure projects. Source: adapted from PIDG (2019).

complete construction enabled by concession finance. Bank loans are paid back by issuing bonds once the construction phase is completed. Such bond refinancing over say, 15–25 years, in the low-risk *mature project phase* can provide a lower cost of capital. Market-making to develop a pipeline of investment opportunities uses a complimentary mix of high-risk capital options in the form of grants, guarantees, equity, and mezzanine financing that can help (Attridge and Gouett 2021): (i) reduce up-front risks in the early phases, (ii) allow banks to recycle loans to new projects, and (iii) galvanise multilateral technical assistance for building bond yield curve benchmarks and de-risking local currency bond issuance of long tenors such as green bonds/resilience bonds (Berensmann et al. 2015; CBI 2015; Mercer 2018; Dasgupta et al. 2019; PIDG 2019; Braga et al. 2021; CBI et al. 2021; Hourcade et al. 2021a,b). Convergence (2019) points to investment from commercial banks with commercial debt of 11–15 years maturity being covered by guarantees. To achieve scale, some have issued special purpose vehicle (SPV) green infrastructure project bonds combining tenors up to 15 years with credit ratings assigned to mobilise investors with community trusts for local participation (Kaminker and Stewart 2012; Mathews and Kidney 2012; Mbeng Mezui and Hundal 2013; Essers et al. 2016; Moody's Investors Service 2016; Ng and Tao 2016; Harber 2017). Bond refinancing could be facilitated through standardised national infrastructure style bonds, national infrastructure funds (Amonya 2009; Ketterer and Powell 2018) and country SPV infrastructure funds issuing bonds (Cavallo and Powell 2019) embedding MDBs.

Existing project risk facilities including guarantees could benefit from coordination, scaling and better reporting frameworks (*high confidence*). Individual and clubs of developed and developing countries currently provide public guarantees (ADB 2015, 2018; IIGCC 2015; Pereira Dos Santos 2018; GGGI 2019; Garbacz et al. 2021). However MDB business models impose limitations on use of guarantees and collaboration with other MDBs (Gropp et al. 2014; Schiff and Dithrich 2017; Lee et al. 2018; Pereira dos Santos and Kearney 2018). Loans continue to dominate as the financial instrument of choice by MDBs and DFIs, with guarantees mobilising the most private finance for OECD reported data, even if their use remains limited (IATFD 2020; OECD 2020c; Attridge and Gouett 2021). Ramping up the use of guarantees to mobilise private investment raises questions around understanding efficacy in the design as there is no one size that fits all and more research is required to better understand this aspect (Convergence 2019). Sample guarantee forms in literature: (i) single-country Sweden and USA DFI forms (SIDA 2016, DCA 2018), (ii) multilateral institution offerings (Pereira Dos Santos 2018; IRENA 2020e), (iii) multi-sovereign guarantees one-stop platforms such as those on the PIDG/GuarantCo (PIDG 2019) and Africa Guarantee Fund owned by DFIs, including the African Development Bank (AfDB), the French Development Agency (AFD), the Nordic Development Fund (NDF), and the KfW Development Bank (AGF 2020), (iv) MIGA, established to provide political risk guarantees (enhanced green MIGA) (Déau and Touati 2018), (v) multilateral partnerships with developing nations via infrastructure funds (Section 15.6.7.2) and green infrastructure options (de Gouvello and Zelenko 2010; Studart and Gallagher 2015), (vi) guarantees embedded in project risk facilities such as currency fund TCX established by 22 DFIs (TCX 2020), and

(vii) ASEAN and African multi-sovereign regional local currency bond guarantee funds and a co-guarantee platform (GGGI 2019; Garbacz et al. 2021). Fossil fuels currently benefit from de-risking tools from export credit agencies (Lawrence and Archer 2021), with questions around sustainable development (Wright 2011); Gupta et al. (2020) argue that these could be deployed for renewable energy. Sample project facilities reflecting the diverse project types across developing country regions can include i) UNEP Seed Capital ii) C40 Cities Facility iii) Blue Natural Capital Facility (IUCN 2021); iv) Clean Cooking Fund (ESMAP 2021) v) opportunities for guarantees in LDCs (Garbacz et al. 2021) vi) World Bank's Renewables Risk Mitigation (GCF 2021) and World Bank's Global Infrastructure Facility (GGGI 2019).. Multilaterals offer credit enhancement to manage both actual and perceived risks: in India's corporate sector, renewable energy SPV project bonds have been guaranteed jointly by ADB and an infrastructure company raising the credit rating from sub-investment grade to investment grade to lower borrowing costs (ADB 2018; Agarwal and Singh 2018; Carrasco 2018).

Investment vehicles into green infrastructure come in various forms (*high confidence*) and can include indirect corporate investment such as bonds; semi-direct investment funds via pooled vehicles such as infrastructure funds and private equity funds and project investment (direct) in green projects through equity and debt including loans, project bonds and green bonds. For pension funds in Australia and Canada, direct investment in infrastructure is about 5% of total AUM (Inderst and Della Croce 2013) whilst less than 1% for OECD pension funds goes to green infrastructure (Kaminker et al. 2013). Some regional developing country institutional investors use a variety of investment vehicles that span SPVs, private equity, domestic and regional local currency bond markets with statutory level mandates to address historic inequities (GEPF 2019). Cross-border collaboration in regional power markets such as Europe's Nordpool; for developing countries could be led by repository of technical partnership from infrastructure funds and multilaterals (Oseni and Pollitt 2016; Juvonen et al. 2019; Chen et al. 2020; Nordpool 2021). Barriers to investments include non-standardised investment vehicles of scale and lack of national infrastructure road maps to give investor confidence in government commitment. Some have set up infrastructure coordinating entities embedding local science and engineering R&D (IPA 2021; National Infrastructure Commission 2021). Arezki et al. (2016) argue that coordination within existing platforms could create a global infrastructure investment platform for de-risking through guarantees and securitisation; Matthäus and Mehling (2020) point to a global guarantee mechanism. Such AAA multilateral approaches create credibility-enhancing effects in developing capital markets. Hourcade et al. (2021a) suggest that the overall economic efficiency could be higher with guarantees calibrated per tonne on an agreed '*social, economic, and environmental value of mitigation actions [and] their co-benefits*' (Article 108, Paris Agreement) basis, which would operate as a notional carbon price (High-Level Commission on Carbon Prices 2017). The grant equivalent of guarantees and induced equity inflows could be far beyond the USD100 billion promise. Such cooperative solutions in adopting development of local capital markets would end the drawbacks of the current plethora of low-scale fragmented project-by-project and 'special-purpose' pilots and programmes.

Harnessing existing bond markets and securities exchanges in nascent markets. The G20 has an action plan to support strengthening local currency bond markets and development of local capital markets is also part of the option for financing UN SDGs in developing countries (UN 2015a, 2019, 2020; IATFD 2016, 2021). Primers are available on bond market development to support policy choices (World Bank and IMF 2001; Silva et al. 2020; World Bank 2020; Adrian et al 2021; IMF and World Bank 2021). Developing government bond yield curves with different maturities can be an important policy objective (*high confidence*). This can support pricing discovery, liquidity (Wooldridge 2001) and can be achieved through step by step tranches from shorter to longer maturities to boost confidence and encourage municipals and other quasi-sovereigns. Money market instruments (such as, green commercial paper) anchor the short end of the yield curve with bonds of varying maturity issued by sovereign/quasi-sovereign entities (national treasuries, SOEs, municipalities) to mobilise investors (Goodfriend 2011; LSEG 2018; Tolliver et al. 2019). A variety of bonds are being used for developing countries including green (Ketterer et al. 2019), blue-water (Roth et al. 2019), transition, SDG/social, biodiversity bonds (Aglionby 2019), green/resilience bonds (AAC 2021); gender bonds (Andrade and Prado 2020) diaspora (LSEG 2017) and infrastructure project bonds (CBK 2021). Local policymakers would gain from technical and financial assistance in building green yield curves, for example with support from multilaterals (EIB 2012; IATFD 2016; Shi 2017; EIB 2018; Impact Investing Institute 2021). Green bonds are one of the most readily accessible to help fund Paris goals (Tolliver et al. 2019; Tuhkanen and Vulturius 2020). Section 15.3.2 refers to the growth in labelled bond markets (CBI 2021a), low borrowing costs and yield curve building in Europe (Bahceli 2020; Serenelli 2021; Stubbington 2021; UK DMO 2021). For developing countries, labelled bonds have mostly been in hard currency (e.g. Smith 2021) despite local currency markets making up more than 80% total debt stock (IMF and World Bank 2016; Silva et al. 2020; Adrian et al 2021; Inderst 2021). The labelled bonds issuance by multilaterals do not currently mobilise the trillion levels needed. Research studies show that participating in green bond markets in part depends on a country having credible NDCs (Tolliver et al. 2020a; Tolliver et al. 2020b) and highlights diverse approaches working together to support local bond market development (Amacker and Donovan 2021; ICMA 2021; IMF and World Bank 2021).

Technical assistance options would benefit from coordination. Labelled bond costs remain high. Developing countries are using fiscal incentives, grants, and guarantees to support nascent bond markets with most taxonomies under development (*high confidence*). Technical assistance requirements to improve the investment climate and bond market development will vary across national capacities. These would benefit from the USD100 billion UNFCCC grant equivalent basis to develop (i) regulatory and policy frameworks; (ii) UN national statistical systems (Singh et al. 2016; MacFeely and Barnat 2017; Paris21 2018; Bleeker and Abdulkadri 2020); (iii) credible NDC and SDG investment plans; (iv) project assessment certification and taxonomies; (v) bond market guidelines; and (vi) public finance management (US DoJ 2009; US DoJ 2019). Other technical assistance channels include diaspora entities, universities and learned societies (ICEAW 2012;

UNFCCC 2021). LDCs supported by humanitarian entities are least likely to have active capital markets (ICRC 2020; IDFC 2020; Cao et al. 2021b). Clubs of LDCs are partnering with AAA MDBs in aggregation approaches (AfDB 2020; GCF 2020b). Some UN entities provide technical assistance on municipal aggregation of projects (UN CDF 2021a), with Africa, LDC, SIDS nations and cities accessing green technical facilities and listings for labelled bonds (C40 Cities Climate Leadership Group 2016; Gorelick 2018; Jackson 2019; FSD Africa and CBI 2020; Gorelick and Walmsley 2020; MoE Fiji 2020; IFC 2021c). Elevated climate risks imperil developing country ability to repay debts (Schmidt 2014; Buhr et al. 2018; Volz et al. 2020; Dibley et al. 2021). To lower overall costs and achieve more, entities have accessed technical assistance, listed local currency labelled bonds, and used credit enhancing bond guarantees, regulatory treatments and philanthropy schemes (Europe 2020 Project Bond Initiative 2012; SBN 2018; Agliardi and Agliardi 2019; Banga 2019). In the regions, China issued guidelines for stock exchanges and regulatory support for green bonds (Cao and Ma 2021), India issued regulations for local issuance of green bonds (CBI 2019a), while in the Latin America and Caribbean region, both plain vanilla and labelled bonds use the same authority (Ketterer et al. 2019). African, LDC and SIDS nations are reviewing ways to harness local exchanges (SSE 2018; GCF 2019; World Bank et al. 2021b; UN CDF 2021b). For taxonomies, the differences reflect the multitude of local Just Transition pathways, some with a purely environmental focus and others incorporating livelihood improvements (ICMA 2021). The sustainable bond market has been expanding as transition bonds become listed in anticipation of future developments (Roos 2021).

Progress towards transparency using scientific-based methods to build trust and accountability. After 60 years of development finance, critics underline limits coming from i) multilaterals model, lack of transparency around aid and debt (Mkandawire 2010; Lee 2017; PWYF 2019; Bradlow 2021; Gianfagna et al. 2021) ii) illicit finance (Plank 1993; Sachs and Warner 2001; Hanlon 2016; US DoJ 2019) iii) lack of developed country commitment to pledges (Nhamo and Nhamo 2016) iv) unregulated players as financial intermediaries in blended finance (Pereira 2017; Donaldson and Hawkes 2018; Attridge and Engen 2019; Tan 2019) v) weak accountability reflected in soft SDG data and vi) burden of responsibility in mobilising Paris and SDG resources to countries with historically soft institutional capacity (Hickel 2015; Donald and Way 2016; Scheyvens et al. 2016; Liverman 2018). Literature around trust in blended finance pinpoints four progress areas in accountability. First, debt transparency through public debt registries, centralised UN legacy debt restructuring and science-centred UN national statistical systems (Donaldson and Hawkes 2018; Jubilee Debt Campaign 2019; Stiglitz and Rashid 2020). Second, international reporting bell-weather could be called upon to produce harmonised mandatory reporting frameworks that capitalise on TCFD to capture climate, debt sustainability (Section 15.6.7.3), SDG and fossil fuels (GISD 2020). Third, standardisation of assessment by third parties of the quantity and values of carbon saved by green projects (Hourcade et al. 2012) and of their contribution to quantified performance biodiversity targets (Finance for Biodiversity Initiative 2021) to facilitate their bundling, securitisation and repackaging in standardised liquid products and bonds (Arezki et al. 2016; Blended Finance Taskforce 2018a).

15.6.8 Facilitating the Development of New Business Models and Financing Approaches

New and innovative business models and financing approaches have emerged to help overcome barriers related to transactions costs by aggregating and/or transferring financing needs and establishing supply of finance for stakeholder groups lacking financial inclusion (*high confidence*).

15.6.8.1 Service-based Business Models in the Energy and Transport Sectors

Energy as a service (EaaS) is a business model whereby customers pay for an energy service without having to make any upfront capital investment (PwC 2014; Hamwi and Lizarralde 2017; Cleary and Palmer 2019). EaaS performance-based contracts can also be a form of 'creative financing' for capital improvement that makes it possible to fund energy upgrades from cost reductions and deployment of decentralised renewable energy (KPMG 2015; Moles-Grueso et al. 2021). Innovation in EaaS has started at the household level, where smart meters using real-time data are used to predict peak demand levels and optimise electricity dispatch (Chasin et al. 2020; Government of UK 2016; Smart Energy International 2018).

Aggregators. An aggregator is a grouping of agents in a power system to act as a single entity when engaging in power system markets (MIT 2016). Aggregators can use operation optimisation platforms to provide real-time operating reserve capacity and a range of balancing services to integrate higher shares of variable renewable energy (Zancanella et al. 2016; Ma et al. 2017; Enbala 2018; Research and Markets 2017; IRENA 2019b). This makes a business case for deferred investments in grid infrastructure (*medium confidence*). Aggregating and managing demand-response of heat systems (micro CHP and heat pumps) has shown reduction in peak demand (TNO 2016).

Peer-to-peer (P2P) electricity trading. Producers and consumers can directly trade electricity with other consumers in an online marketplace to avoid the relatively high tariffs and the relatively low buy-back rates of traditional utilities (Liu et al. 2019; IRENA 2020f). P2P models trading with distributed energy resources reduce transmission losses and congestion (Mengelkamp et al. 2018; SEDA 2020; Lumenaza 2020; Sonnen 2020; UNFCCC 2020).

Community ownership models. Community ownership models refer to the collective ownership and management of energy-related assets with lower levels of investment, usually distributed renewable energy resources but also recently in heating systems and energy services (e.g., storage and charging) (Gall 2018; IRENA 2018; Kelly and Hanna 2019; Singh et al. 2019; Bisello et al. 2021; Maclurcan and Hinton 2021). Community ownership projects may need significant upfront investments, and the ability of communities to raise the required financing might prove insufficient, which can be supported by microcredits in the initial stages of the projects (Aitken 2013; Federici 2014; REN21 2016; Rescoop 2020).

Payment method: Pay-as-you-go (PayGo). PayGo business models emerged to address the energy access challenge and provide chiefly solar energy at affordable prices, using mobile telecommunication to facilitate payment through instalments (Yadav et al. 2019). However, PayGo has the technology and product risk, requires a financially viable and large customer base, and the system supplier must provide a significant portion of the finance and requires substantial equity and working capital (C40 Cities Climate Leadership Group 2018).

Transport sector business models. Analog to EaaS, mobility as a service (MaaS) offers a business model whereby customers pay for a mobility service without making any upfront capital investment (e.g., buying a car). MaaS tends to deliver significant urban benefits (e.g., cleaner air) and brings in efficiency gains in the use of resources (*high confidence*). However, the switch to MaaS hardly improves the carbon footprint and further tempted on-demand mobility is likely to nurture carbon emissions (Suatmadi et al. 2019). Therefore, to support climate change mitigation, MaaS must be integrated with the deployment of smart charging of electric (autonomous) vehicles coupled to renewable energy sources (IRENA 2019d; Jones and Leibowicz 2019).

Financial technology applications to climate change. Financial technology, abbreviated as 'fintech', applies to data-driven technological solutions that aim to improve financial services (Dorffleitner et al. 2017; Lee and Shin 2018; Schueffel 2018). Fintech can enhance climate investment in innovative financial products and build trust through data, but also presents some challenges including potentially significant emissions from increased energy use with distributed transactions (Lei et al. 2021). Blockchain is a key fintech that secures individual transactions in a distributed system, which can have many applications with high impact potential but is also associated with uncertainty (OECD 2019c; World Energy Council 2019). Fintech applications with climate change mitigation potential have been growing recently, including tracking payment or asset history for credit scoring in AFOLU activities (Nassiry 2018; Davidovic et al. 2019), blockchain supported grid transactions (Livingston et al. 2018), carbon accounting throughout value chains (World Bank 2018b), or transparency and verification mechanisms for green financial instrument investors (Kyriakou et al. 2017; Stockholm Green Digital Finance 2017). Generally, blockchain and digital currency applications are not well covered by governance systems (Tapscott and Kirkland 2016; Nassiry 2018), which could lead to problems with security (Davidovic et al. 2019), and some licensing and prudential supervision frameworks are in flux.

15.6.8.2 Nature-Based Solutions Including REDD+

Nature-based solutions are 'actions to protect, sustainably manage and restore natural or modified ecosystems that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits' (Cohen-Shacham et al. 2016). Nature-based solutions consist of a wide range of measures including ecosystem-based mitigation and adaptation.

The studies on investment and finance for nature-based solutions is still limited. However, frameworks and schemes to incentivise the implementation of nature-based solutions, such as reducing emissions from deforestation and forest degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries (REDD+), which contributes to climate change mitigation, has been actively discussed under the UNFCCC, with lessons from finance for REDD+ being available.

If effectively implemented, nature-based solutions can be cost-effective measures and able to provide multiple benefits, such as enhanced climate resilience, enhanced climate change mitigation, biodiversity habitat, water filtration, soil health, and amenity values (*high confidence*) (Griscom et al. 2017; Keesstra et al. 2018; OECD 2019d; Griscom et al. 2020; Dasgupta 2021).

Nature-based solutions have large potential to address climate change and other sustainable development issues (*high confidence*). Nature-based solutions are undercapitalised and the limited investment and finance, especially limited private capital, is widely recognised as one of the main barriers to the implementation and monitoring of the nature-based solutions (Seddon et al. 2020; Toxopeus and Polzin 2021; UNEP et al. 2021). Finance and investment models that generate their own revenues or consistently save costs are necessary to reduce dependency on grants (Schäfer et al. 2019; Wamsler et al. 2020).

REDD+. REDD+ can significantly contribute to climate change mitigation and also produce other co-benefits like climate change adaptation, biodiversity conservation, and poverty reduction, if well-implemented (*high confidence*) (Milbank et al. 2018; Morita and Matsumoto 2018). We use the term REDD+ broadly, not limited to REDD+ implemented under the UNFCCC decisions, including Warsaw Framework for REDD+ (Chapter 14), but include voluntary REDD+ projects, such as projects which utilise voluntary carbon markets. Finance is a core element that incentivises and implements REDD+ activities. Various financial sources are financing REDD+ activities, including bilateral and multilateral, public and private, and international and domestic sources, with linking with several finance approaches/mechanisms including results-based finance and voluntary carbon markets (FAO 2018). However, there is lack of sufficient finance for REDD+ (Lujan and Silva-Chávez 2018; Maguire et al. 2021). REDD+ under the UNFCCC is implemented in three phases: readiness, implementation, and results-based payment phases. The Ecosystem Marketplace identified that at least USD5.4 billion in REDD+ in three phases funding has been committed through multiple development finance institutions so far (Maguire et al. 2021), and public funds are main sources that are supporting three phases, and most of the REDD+ finance was spent on the readiness phase (Atmadja et al. 2018; Lujan and Silva-Chávez 2018; Watson and Schalatek 2021). There is a significant gap between the existing finance and finance needs of REDD+ in each phase (Lujan and Silva-Chávez 2018). Furthermore, private sector contributions to REDD+ are currently limited mostly to the project-scale payments for carbon offsets/units through voluntary carbon markets (McFarland 2015; Lujan and Silva-Chávez 2018).

Current main challenges of REDD+ finance include the uncertainty of compliance carbon markets (which allow regulated entities to obtain and surrender emissions allowances or offsets to meet regulatory emissions reduction targets) (Maguire et al. 2021), as well as limited engagement of the private sector in REDD+ finance (*high confidence*). With regard to the compliance carbon markets, at the international level, integrating climate cooperation through carbon markets into Article 6 of the Paris Agreement and including REDD+ has potential to enable emission reduction in more cost-effective ways, while the links between carbon markets and REDD+ under Article 6 is under discussion at the UNFCCC (Environmental Defense Fund 2019; Maguire et al. 2021) (Chapter 14). At the national and subnational levels, although compliance carbon markets such as in New Zealand, Australia and Colombia allow forest carbon units, how REDD+ will be dealt in the national and subnational government-led compliance carbon markets is uncertain (Streck 2020; Maguire et al. 2021). As for limited engagement of the private sector in REDD+ finance, there are various reasons why mobilising more private finance in REDD+ is difficult (Dixon and Challies 2015; Laing et al. 2016; Golub et al. 2018; Ehara et al. 2019; Streck 2020). The challenges include the needs of a clear understanding of carbon rights and transparent regulation on who can benefit from national REDD+ (Streck 2020); a clear regulatory framework and market certainty (Dixon and Challies 2015; Laing et al. 2016; Golub et al. 2018; Ehara et al. 2019); strong forest governance (Streck 2020), and implementation of REDD+ activities at national and subnational levels. Other challenges are associated with the nature of forest-based mitigation activities, the costs and complexity of monitoring, reporting and verification of REDD+ activities, because of the need to consider the risks of permanence, carbon leakage, and precisely determine and monitor the forest carbon sinks (van der Gaast et al. 2018; Yanai et al. 2020). Although REDD+ has many challenges to mobilise more private finance, there is discussion on exploring other finance opportunities for the forest sector, such as building new blended finance models combining different funding sources like public and private finance (Streck 2016; Rode et al. 2019), and developing enhanced bonds for forest-based mitigation activities (World Bank 2017).

Private finance opportunities for nature-based solutions. The development of nature-based solutions faces barriers that relate to the value proposition, value delivery and value capture of nature-based solutions business models and sustainable sources of public/private finance to tap into (*high confidence*) (Toxopeus and Polzin 2017; Mok et al. 2021). However, the demand for establishing new finance and business models to attract both public and private finance to nature-based solutions is increasing in a wide range of topics such as urban areas, forestry and agriculture sectors, and blue natural capital including mangroves and coral reefs (Toxopeus and Polzin 2017; EIB 2019; Cziesielski et al. 2021; Mok et al. 2021; Thiele et al. 2021; UNEP et al. 2021). Furthermore, the recognition of the needs of financial institutions to identify the physical, transition and reputational risks resulting from not only climate change but also loss of biodiversity is gradually increasing (De Nederlandsche Bank and PBL Netherlands Environmental Assessment Agency 2020; Dasgupta 2021; TNFD 2021). Development of finance and business models for nature-based solutions needs to be explored, for example through utilising a wide range of financial instruments (e.g., equity, loans,

bonds, and insurance), and creating standard metrics, baselines and common characteristics for nature-based solutions to promote the creation of a new asset class (Thiele et al. 2021; UNEP et al. 2021).

15.6.8.3 Exploring Gender-responsive Climate Finance

Global and national recognition of the lack of finance for women has led to increasing emphasis on financial inclusion for women (*high confidence*). Currently, it is estimated that 980 million women are excluded from formal financial system (Miles and Wiedmaier-Pfister 2018); and there is a 9% gender gap in financial access across developing countries (Demirguc-Kunt et al. 2018). This gender gap is the percentage difference between men and women with bank accounts as measured and reported in the Global Financial Inclusion (Global Findex) database. Policies and frameworks to expand and enhance financial inclusion also extend to the area of climate finance (*high confidence*). Since AR5, there remain many questions and not enough evidence on the gender, distribution and allocative effectiveness of climate finance in the context of gender equality and women's empowerment (Williams M., 2015; Chan et al. 2018; Wong et al. 2019). Nonetheless, the existing global policy framework (entry points, policy priorities, etc.) of climate funds is gradually improving in order to support women's financial inclusion in both the public and the private dimensions of climate finance/investment (Schalatek 2015; Chan et al. 2018; Schalatek 2020). At the level of public multilateral climate funds, there have been significant improvements in integrating gender equality and women's empowerment issues in the governance structures, policies, project approval and implementation processes of existing multilateral climate funds such as the UNFCCC's funds managed by the Global Environment Facility, the Green Climate Fund and the World Bank's CIFs (*high confidence*) (Schalatek 2015; Williams M., 2015; Sellers 2016; GCF 2017). But according to a recent evaluation report, the integration of gender into operational policies and programmes is fragmented and there is lack of an 'adequate, systematic and comprehensive gender equality approach for the allocation and distribution of funds for projects and programmes on the ground' (GEF Independent Evaluation Office 2017; Schalatek 2018). The review found that 'almost half of the analysed sample of 70 climate projects were judged to be largely gender-blind, and only 5% considered to have successfully mainstreamed gender, including in two Least Developed Countries Fund adaptation projects' (GEF Independent Evaluation Office 2017; Schalatek 2018). While the GCF requires funding proposals to consider gender impact as part of their investment framework,¹⁶ the fund does not have its own funding stream targeted to women's project on the ground, nor is there as yet an evaluation as to how entities are actually implementing gender action plan in the projects. In the case of the CIFs, as noted by Schalatek (2018), 'gender is not included in the operational principles of the Pilot Program on Climate Resilience (PPCR), which funds programmatic adaptation portfolios in a few developing countries, although most pilot countries have

included some gender dimensions'. And, 'gender is not integrated into the operations of the Clean Technology Fund (CTF), which finances large-scale mitigation in large economies and accounts for 70% of the CIFs' pledged funding portfolio of 8.2 billion USD' (Schalatek 2018). However, both the Forest Investment Program (FIP) and the Scaling-Up Renewable Energy in Low-Income Countries Program (SREP) have integrated gender equality as either a co-benefit or core criteria of these programmes (Schalatek 2018).

Overall, efforts to promote gender responsive/sensitive climate finance, at national and local levels, both in the public and private dimensions and more specifically in mitigation-oriented sectors such as clean and renewable energy, remain deficient (*high confidence*). Recent developments in the capital markets in the areas of social bond are focused around gender bonds – debt instruments targeted to activities and behaviours that are relevant to gender equality and women's empowerment. These bonds are aligned with Sustainability-linked Bonds as well as Social Bonds Principles of the International Capital Market Association. Issuances of gender-labelled bonds are increasing in the Asia Pacific region (the most comprehensive initiative is the Impact Investment Exchange's (IIX) multi-country USD150 million Women's Livelihood Bond¹⁷) and in Latin America, Colombia, Mexico and Panama each have gender bond issuances). Additionally, a few developing countries, such as Pakistan (May 2021) and Morocco (March 2021) have issued gender bond guidelines for financial market participants.

Linkage to sectoral climate change issues and gender and climate finance. Subsets of actions designed to enhance women's more formal integration into climate policies, programmes and actions by the global private sector include: investment in clean energy, redirecting funds to support women and vulnerable regions as a component of social and green bonds as well as insurance for climate risk management. In the latter context, insurance providers are arguing that 'given the fact that women are disproportionately affected by climate change, there could be new finance innovations to address this gap'. (Miles and Wiedmaier-Pfister 2018). AXA and IFC estimate that the global women's insurance market has the opportunity to grow to three times its current size, to USD1.7 trillion by 2030 (AXA Group et al. 2015; GIZ et al. 2017). However, across the board, and in particular with regard to public funds, despite improvements in the substantive gender sensitisation and operational gender responsiveness of multilateral and bilateral climate finance funds operations, current flows of public and climate finance do not seem to be going to women and local communities in significant amounts (Chan et al. 2018; Schalatek 2020). At the same time, evaluations of the effectiveness of climate finance show that equitable flow of climate finance can play an important role in levelling the playing field and in enabling women and men to successfully respond to climate change and to enable the success and sustainability of local response in ensuring effective and sustainable

¹⁶ Notably, the GCF provides guidance to Accredited Entities submitting funding proposals on the inclusion of an initial gender and social assessment during the project planning, preparation and development stage and a gender and social inclusion action plan at the project preparation stage.

¹⁷ The Women's Livelihood Bond (WLB) series has been on the market since 2017 when WLB1 was launched. WLB2 issuance of USD12 million arrived January 2020. WLB3 was launched December 2020 to support 180,000 underserved women and women entrepreneurs in the Asia Pacific region to respond, to recover from, and to build resilience in the aftermath of the COVID-19 pandemic (Rockefeller Foundation and Shujog 2016; IIX 2020).

climate strategies that can contribute to the global goals of the Paris Agreement (Minniti and Naudé 2010; Bird et al. 2013; Barrett 2014; Eastin 2018). This is particularly so in the case of female-owned

MSMEs, who, the literature increasingly shows, are key to promoting resilience at micro and macro scale in many developing countries (Omolo et al. 2017; Atela et al. 2018; Crick, F. et al. 2018).

Frequently Asked Questions (FAQs)

FAQ 15.1 | What's the role of climate finance and the finance sector for a transformation towards a sustainable future?

The Paris Agreement has widened the scope of all financial flows from climate finance only to the full alignment of finance flows with the long-term goals of the Paris Agreement. While climate finance relates historically to the financial support of developed countries to developing countries, the Paris Agreement and its Article 2.1(c) have developed a new narrative that goes much beyond traditional flows and relates to all sectors and actors. Finance flows are consistent when the effects are either neutral with or without positive climate co-benefits to climate objectives; or explicitly targeted to climate benefits in adaptation and/or mitigation result areas. Climate-related financial risk is still massively underestimated by financial institutions, financial decision-makers more generally and also among public sector stakeholders, limiting the sector's potential of being an enabler of the transition. The private sector has started to recognise climate-related risks and consequently redirect investment flows. Dynamics vary across sectors and regions with the financial sector being an enabler of transitions in only some selected (sub-)sectors and regions. Consistent, credible, timely and forward-looking political leadership remains central to strengthen the financial sector as enabler.

FAQ 15.2 | What's the current status of global climate finance and the alignment of global financial flows with the Paris Agreement?

There is no agreed definition of climate finance. The term 'climate finance' is applied to the financial resources devoted to addressing climate change by all public and private actors from global to local scales, including international financial flows to developing countries to assist them in addressing climate change. Total climate finance includes all financial flows whose expected effect aims to reduce net greenhouse gas (GHG) emissions and/or to enhance resilience to the impacts of current and projected climate change. This includes private and public funds, domestic and international flows and expenditures. Tracking of climate finance flows faces limitations, in particular for national climate finance flows.

Progress on the alignment of financial flows with low GHG emissions pathways remains slow. Annual global climate finance flows are on an upward trend since the Fifth Assessment Report, according to the Climate Policy Initiative reaching more than USD630 billion in 2019/2020, however, growth has likely slowed down and flows remain significantly below needs. This is driven by barriers within and outside the financial sector. More than 90% of financing is allocated to mitigation activities despite the strong economic rationale of adaptation action. Adjusting for higher estimates on current flows for energy efficiency based on International Energy Agency data, the dominance of mitigation becomes even stronger. Persistently high levels of both public and private fossil-fuel related financing as well as other misaligned flows continue to be of major concern despite recent commitments. Significant progress has been made in the commercial finance sector with regard to the awareness of climate risks resulting from inadequate financial flows and climate action. However, a more consequent investment and policy decision-making that enables a rapid redirection of financial flows is needed. Regulatory support as a catalyser is an essential driver of such redirections. Dynamics across sectors and regions vary, with some being better positioned to close financing gaps and to benefit from an enabling role of finance in the short-term.

FAQ 15.3 | What defines a financing gap, and where are the critically identified gaps?

A financing gap is defined as the difference between current flows and average needs to meet the long-term goals of the Paris Agreement. Gaps are driven by various barriers inside (short-termism, information gaps, home bias, limited visibility of future pipelines) and outside (e.g., missing pricing of externalities, missing regulatory frameworks) of the financial sector. Current mitigation financing flows come in significantly below average needs across all regions and sectors despite the availability of sufficient capital on a global basis. Globally, yearly climate finance flows have to increase by a factor between three and six to meet average annual needs between 2020 and 2030.

Gaps are in particular concerning for many developing countries, with COVID-19 exacerbating the macroeconomic outlook and fiscal space for governments. Also, limited institutional capacity represents a key barrier for many developing countries, burdening risk perceptions and access to appropriately priced financing as well as limiting their ability to actively manage the transformation. Existing fundamental inequities in access to finance, as well as its terms and conditions, and countries' exposure to physical impacts of climate change, overall result in a worsening outlook for a global just transition.

Executive Summary

Innovation in climate mitigation technologies has seen enormous activity and significant progress in recent years. Innovation has also led to, and exacerbated, trade-offs in relation to sustainable development (*high confidence*).

Innovation can leverage action to mitigate climate change by reinforcing other interventions. In conjunction with other enabling conditions, innovation can support system transitions to limit warming and help shift development pathways. The currently widespread implementation of solar photovoltaic (solar PV) and light-emitting diodes (LEDs), for instance, could not have happened without technological innovation (*high confidence*). Technological innovation can also bring about new and improved ways of delivering services that are essential to human well-being. At the same time as delivering benefits, innovation can result in trade-offs that undermine both progress on mitigation and progress towards other Sustainable Development Goals (SDGs). Trade-offs include negative externalities – for instance, greater environmental pollution and social inequalities – rebound effects leading to lower net emission reductions or even increases in emissions, and increased dependency on foreign knowledge and providers (*high confidence*). Effective governance and policy has the potential to avoid and minimise such misalignments (*medium evidence, high agreement*). {16.1, 16.2, 16.3, 16.4, 16.5.1, 16.6}

A systemic view of innovation to direct and organise the processes has grown over the last decade. This systemic view of innovation takes into account the role of actors, institutions and their interactions, and can inform how innovation systems that vary across technologies, sectors and countries, can be strengthened (*high confidence*). Where a systemic view of innovation has been taken, it has enabled the development and implementation of indicators that are better able to provide insights into innovation processes. This, in turn, has enabled the analysis and strengthening of innovation systems. Traditional quantitative innovation indicators mainly include research and development (R&D) investments and patents. Systemic indicators of innovation, however, go well beyond these approaches. They include structural innovation system elements including actors and networks, as well as indicators for how innovation systems function, such as access to finance, employment in relevant sectors, and lobbying activities. For example, in Latin America, monitoring systemic innovation indicators for the effectiveness of agroecological mitigation approaches has provided insights on the appropriateness and social alignment of new technologies and practices. Climate-energy-economy models, including integrated assessment models, generally employ a stylised and necessarily incomplete view of innovation, and have yet to incorporate a systemic representation of innovation systems. {16.2, 16.2.4, 16.3, 16.3.4, 16.5, Table 16.7, Box 16.1, Box 16.3, Box 16.10}

A systemic perspective on technological change can provide insights to policymakers supporting their selection of effective innovation policy instruments (*high confidence*). A combination of scaled-up innovation investments with demand-pull interventions can achieve faster technology unit cost reductions and more rapid scale-up than either approach in isolation (*high confidence*). These

innovation policy instruments would nonetheless have to be tailored to local development priorities, to the specific context of different countries, and to the technology being supported. The timing of interventions and any trade-offs with sustainable development also need to be addressed. Public R&D funding and support, as well as innovation procurement, have proven valuable for fostering innovation in small to medium cleantech firms. Innovation outcomes of policy instruments not necessarily aimed at innovation, such as feed-in tariffs, auctions, emissions trading schemes, taxes and renewable portfolio standards, vary from negligible to positive for climate change mitigation. Some specific designs of environmental taxation can also result in negative distributional outcomes. Most of the available literature and evidence on innovation systems come from industrialised countries and larger developing countries. However, there is a growing body of evidence from developing countries and Small Island Developing States (SIDS). {16.4, 16.4.4.3, 16.4.4.4, 16.5, 16.7}

Experience and analyses show that technological change is inhibited if technological innovation system functions are not adequately fulfilled. This inhibition occurs more often in developing countries (*high confidence*). Examples of such functions are knowledge development, resource mobilisation, and activities that shape the needs, requirements and expectations of actors within the innovation system (guidance of the search). Capabilities play a key role in these functions, the build-up of which can be enhanced by domestic measures, but also by international cooperation (*high confidence*). For instance, innovation cooperation on wind energy has contributed to the accelerated global spread of this technology. As another example, the policy guidance by the Indian government, which also promoted development of data, testing capabilities and knowledge within the private sector, has been a key determinant of the success of an energy-efficiency programme for air conditioners and refrigerators in India. {16.3, 16.5, 16.6, Cross-Chapter Box 12 in this chapter, Box 16.2}

Consistent with innovation system approaches, the sharing of knowledge and experiences between developed and developing countries can contribute to addressing global climate and SDGs. The effectiveness of such international cooperation arrangements, however, depends on the way they are developed and implemented (*high confidence*). The effectiveness and sustainable development benefits of technology sharing under market conditions appear to be determined primarily by the complexity of technologies, local capabilities and the policy regime. This suggests that the development of planning and innovation capabilities remains necessary, especially in least-developed countries and SIDS. International diffusion of low-emission technologies is also facilitated by knowledge spillovers from regions engaged in clean R&D (*medium confidence*). {16.6}

The evidence on the role of intellectual property rights (IPR) in innovation is mixed. Some literature suggests that it is a barrier, while other sources suggest that it is an enabler to the diffusion of climate-related technologies (*medium confidence*). There is agreement that countries with well-developed institutional capacity may benefit from a strengthened IPR regime,

but that countries with limited capabilities might face greater barriers to innovation as a consequence. This enhances the continued need for capacity building. Ideas to improve the alignment of the global IPR regime and address climate change include specific arrangements for least-developed countries, case-by-case decision-making and patent-pooling institutions. {16.2.3.3, 16.5, Box 16.9}

Although some initiatives have mobilised investments in developing countries, gaps in innovation cooperation remain, including in the Paris Agreement instruments. These gaps could be filled by enhancing financial support for international technology cooperation, by strengthening cooperative approaches, and by helping build suitable capacity in developing countries across all technological innovation system functions (*high confidence*). The implementation of current arrangements of international cooperation for technology development and transfer, as well as capacity building, are insufficient to meet climate objectives and contribute to sustainable development. For example, despite building a large market for mitigation technologies in developing countries, the lack of a systemic perspective in the implementation of the Clean Development Mechanism, operational since the mid-2000s, has only led to some technology transfer, especially to larger developing countries, but limited capacity building and minimal technology development (*medium confidence*). In the current climate regime, a more systemic approach to innovation cooperation could be introduced by linking technology institutions, such as the Technology Mechanism, and financial actors, such as the financial mechanism. {16.5.3}

Countries are exposed to sustainable development challenges in parallel with the challenges that relate to climate change. Addressing both sets of challenges simultaneously presents multiple and recurrent obstacles that systemic approaches to technological change could help resolve, provided they are well managed (*high confidence*). Obstacles include both entrenched power relations dominated by vested interests that control and benefit from existing technologies, and governance structures that continue to reproduce unsustainable patterns of production and consumption (*medium confidence*). Studies also highlight the potential for cultural factors to strongly influence the pace and direction of technological change. Sustainable solutions require adoption and mainstreaming of locally novel technologies that can meet local needs, and simultaneously address the SDGs. Acknowledging the systemic nature of technological innovation, which involves many levels of actors, stages of innovation and scales, can lead to new opportunities to shift development pathways towards sustainability. {16.4, 16.5, 16.6}

An area where sustainable development, climate change mitigation and technological change interact is digitalisation. Digital technologies can promote large increases in energy efficiency through coordination and an economic shift to services, but they can also greatly increase energy demand because of the energy used in digital devices. System-level rebound effects may also occur (*high confidence*). Digital devices, including servers, increase pressure on the environment due to the demand for rare metals and end-of-life disposal. The absence

of adequate governance in many countries can lead to harsh working conditions and unregulated disposal of electronic waste. Digitalisation also affects firms' competitiveness, the demand for skills, and the distribution of, and access to, resources. The existing digital divide, especially in developing countries, and the lack of appropriate governance of the digital revolution can hamper the role that digitalisation could play in supporting the achievement of stringent mitigation targets. At present, the understanding of both the direct and indirect impacts of digitalisation on energy use, carbon emissions and potential mitigation, is limited (*medium confidence*). {Cross-Chapter Box 11 in this chapter, 16.2}

Strategies for climate change mitigation can be most effective in accelerating transformative change when actions taken to strengthen one set of enabling conditions also reinforce and strengthen the effectiveness of other enabling conditions (*medium confidence*). Applying transition or system dynamics to decisions can help policymakers take advantage of such high-leverage intervention points, address the specific characteristics of technological stages, and respond to societal dynamics. Inspiration can be drawn from the global unit cost reductions of solar PV, which were accelerated by a combination of factors interacting in a mutually reinforcing way across a limited group of countries (*high confidence*). {Box 16.4, Cross-Chapter Box 12 in this chapter}

Better and more comprehensive data on innovation indicators can provide timely insights for policymakers and policy design locally, nationally and internationally, especially for developing countries, where such insights are missing more often. Data needed include those that can show the strength of technological, sectoral and national innovation systems. It is also necessary to validate current results and generate insights from theoretical frameworks and empirical studies for developing countries contexts. Innovation studies on adaptation and mitigation other than energy and ex-post assessments of the effectiveness of various innovation-related policies and interventions, including R&D, would also provide benefits. Furthermore, methodological developments to improve the ability of integrated assessment models (IAMs) to capture energy innovation system dynamics, and the relevant institutions and policies (including design and implementation), would allow for more realistic assessment. {16.2, 16.3, 16.7}

16.1 Introduction

Technological change and innovation are considered key drivers of economic growth and social progress (Brandão Santana et al. 2015; Heeks and Stanforth 2015). Increased production and consumption of goods and services creates economic benefits through higher demands for improved technologies (Gossart 2015). Since the Industrial Revolution, however, and notwithstanding the benefits, this production and consumption trend and the technological changes associated with it have also come at the cost of long-term damage to the life support systems of our planet (Alarcón and Vos 2015; Steffen et al. 2015). The significance of such impacts depends on the technology, but also on the intrinsic characteristics of the country or region analysed (Brandão Santana et al. 2015).

Other chapters in this volume have discussed technological change in various ways, including as a framing issue (Chapter 1), in the context of specific sectors (Chapters 6–11), for specific purposes (Chapter 12) and as a matter of policy, international cooperation and finance (Chapters 13–15). Chapter 2 discusses past trends in technological change and chapters 3 and 4 discuss it in the context of future modelling. In general, implicitly or explicitly, technological change is assigned an important role in climate change mitigation and achieving sustainable development (Thacker et al. 2019), as also discussed in past IPCC reports (IPCC 2014, 2018a). Chapter 16 describes how a well-established innovation system at a national level, guided by well-designed policies, can contribute to achieving mitigation and adaptation targets along with broader Sustainable Development Goals (SDGs), while avoiding undesired consequences of technological change.

The environmental impacts of social and economic activities, including emissions of greenhouse gases (GHGs), are greatly influenced by the rate and direction of technological changes (Jaffe et al. 2000). Technological changes usually designed and used to increase productivity and reduce the use of natural resources can lead to increased production and consumption of goods and services through different rebound effects that diminish the potential benefits of reducing the pressure on the environment (Kemp and Soete 1990; Grübler 1998; Sorrell 2007; Barker et al. 2009; Gossart 2015).

Those environmental impacts depend not only on which technologies are used, but also on how they are used (Grübler et al. 1999a).

Technological change is not exogenous to social and economic systems; technologies are not conceived, selected, and applied autonomously (Grubler et al. 2018). Underlying driving forces of the problem, such as more resource-intensive lifestyles and larger populations (Hertwich and Peters 2009; UNEP 2014), remain largely unchallenged. Comprehensive knowledge of the direct and indirect effects of technological changes on physical and social systems could improve decision-making, including in those cases where technological change mitigates environmental impacts.

A sustainable global future for people and nature requires rapid and transformative societal change by integrating technical, governance (including participation), financial and societal aspects of the solutions to be implemented (Sachs et al. 2019; Pörtner et al. 2021). A growing body of interdisciplinary research from around the world can inform implementation of adaptive solutions that address the benefits and drawbacks of linkages in social-ecological complexity, including externalities and rebound effects from innovation and technological transformation (Balvanera et al. 2017; Pörtner et al. 2021).

Technological change and transitional knowledge can reinforce each other. The value of traditional wisdom and its technological practices provide examples of sustainable and adaptive systems that could potentially adapt to and mitigate climate change (Kuoljok 2019; Singh et al. 2020). Peasants and traditional farmers have been able to respond well to climate changes through their wisdom and traditional practices (Nicholls and Alteri 2013). The integration of the traditional wisdom with new technologies can offer new and effective solutions (Galloway McLean 2010).

Achieving climate change mitigation and other SDGs thus also requires rapid diffusion of knowledge and technological innovations. However, these are hampered by various barriers, some of which are illustrated in Table 16.1 (Markard et al. 2020).

The literature has been growing rapidly over the past decades on how, in a systemic way, the barriers to sustainability transition can be overcome in various circumstances. A central element is that national systems of innovation can help achieve both climate change goals and SDGs, by integrating new ideas, devices, resources, new and traditional knowledge, and technological changes for more effective and adaptive solutions (Lundvall 1992). At the organisational level, innovation is seen

Table 16.1 | Overview of challenges to accelerated diffusion of technological innovations. Source: based on Markard et al. (2020).

Challenges	Description	Examples
Innovations in whole systems	Since entire systems are changing, changes in system architecture are also needed, which may not keep pace.	Decentralisation of electricity supply and integration of variable sources.
Interaction between multiple systems and subsystems	Simultaneous, accelerating changes multiple systems or sectors, vying for the same resources and showing other interactions.	Electrification of transport, heating and industry all using the same renewable electricity source.
Industry decline and incumbent resistance	Decline of existing industries and businesses can lead to incumbents slowing down change, and resistance, e.g., from unions or workers.	Traditional car industry leading to factory closures, demise of coal mining and coal-fired power generation leading to local job loss.
Consumers and social practices	Consumers need to change practices and demand patterns.	Reduced car ownership in a sharing economy, trip planning for public and non-motorised transport, fuelling practices in electric driving.
Coordination in governance and policy	Increasing complexity of governance requires coordination between multiple levels of government and a multitude of actors relevant to the transition, e.g., communities, financial institutions, private sector.	Multilevel governance between European Commission and member states in Energy Union package.

as a process that can bring value by means of creating more effective products, services, processes, technologies, policies and business models that are applicable to commercial, business, financial and even societal or political organisations (Brooks 1980; Arthur 2009).

The literature refers to the terms ‘technology push’, ‘market pull’, ‘regulatory push-pull’, and ‘firm specific factors’ as drivers for innovation, mostly to inform policymakers (Zubeltzu-Jaka et al. 2018). There has also been growing interest in social drivers, motivated by the recognition of social issues, such as unemployment and public health, linked to the deployment of innovative low-carbon technologies (Altantsetseg et al. 2020). Policy and social factors and the diverse trajectories of innovation are influenced by regional and national conditions (Tariq et al. 2017), and such local needs and purposes need to be considered in crafting international policies aimed at fostering the global transition towards increased sustainability (Caravella and Crespi 2020). From this standpoint, a multidimensional, multi-actor, systemic innovation approach would be needed to enhance global innovation diffusion (de Jesus and Mendonça 2018), especially if this is to lead to overall sustainability improvements rather than result in new sustainability challenges.

Policies to mitigate climate change do not always take into account the effects of mitigation technologies on other environmental and social challenges (Arvesen et al. 2011). Policies also often disregard the strong linkages between technological innovation and social innovation; the latter is understood to be the use of soft technologies that brings about transformation through establishing new institutions, new practices, and new models to create a positive societal impact, characterised by collaboration that crosses traditional roles and boundaries, between citizens, civil society, the state, and the private sector (Reynolds et al. 2017). Market forces do not provide sufficient incentives for investment in development or diffusion of technologies, leaving a role for public policy to create the conditions to assure a systemic innovation approach (Popp 2010; Popp and Newell 2012). Moreover, public action is more than just addressing market failure, it is an unalienable element of an innovation system (Mazzucato 2013).

Coupling technological innovation with sustainable development and the SDGs would need to address overall social, environmental, and economic consequences, given that public policy is intertwined with innovation, technological changes and other factors in a complex manner. Chapter 16 is organised in the following manner to provide an overview of innovation and technology development and transfer for climate change and sustainable development.

Section 16.2 discusses drivers of innovation process, including macro factors that can redirect technological change towards low-carbon options. Representations of these drivers in mathematical and statistical models allow for explaining the past and constructing projections of future technological change. They also integrate the analysis of drivers and consequences of technological change within economic-energy-economy (or integrated assessment) models (Chapter 3). The section also describes the different phases of innovation and metrics, such as the widely used but also criticised technology readiness levels (TRLs).

Section 16.3 discusses innovation as a systemic process based on recent literature. While the innovation process is often stylised as a linear process, innovation is now predominantly seen as a systemic process in that it is a result of actions by, and interactions among, a large set of actors, whose activities are shaped by, and shape, the context in which they operate and the user group with which they are engaging.

Section 16.4 presents innovation and technology policy, including technology push (e.g., publicly funded R&D) and demand-pull (e.g., governmental procurement programmes) instruments that address potential market failures related to innovation and technology diffusion. The section also assesses the cost-effectiveness of innovation policies as well as other policy assessment criteria introduced in Chapter 13.

Section 16.5 assesses the role of international cooperation in technology development and transfer, in particular the mechanisms established under the UN Framework Convention on Climate Change (UNFCCC), but also other international initiatives for technology cooperation. The discussion on international cooperation includes information exchange, research, development and demonstration cooperation, access to financial instruments, intellectual property rights, as well as promotion of domestic capacities and capacity building.

Section 16.6 describes the role of technology in sustainable development, including unintended effects of technological changes, and synthesises the chapter.

Finally, Section 16.7 discusses gaps in knowledge emerging from this chapter.

16.2 Elements, Drivers and Modelling of Technology Innovation

Models of the innovation process, its drivers and incentives provide a tool for technology assessment, constructing projections of technological change and identifying which macro conditions facilitate development of low-carbon technologies. The distinction between stages of the innovation process allows for assessment of technology readiness (Section 16.2.1). Qualitative and quantitative analysis of the main elements underpinning innovation – research and development (R&D), learning by doing, and spillovers – allows for an explanation of past and projected future technological changes (Section 16.2.2). In addition, general purpose technologies can play a role in climate change mitigation.

In the context of mitigation pathways, the feasibility of any emission reduction targets depends on the ability to promote innovation in low- and zero-carbon technologies, as opposed to any other technology. For this reason, Section 16.2.3 reviews the literature of the levers influencing the *direction* of technological change in favour of low- and zero-carbon technologies. Moreover, representation of drivers in mathematical and statistical models from Section 16.2.2 allows integration of its analysis with economic and climate effects

within integrated assessment models (IAMs), hence permitting more precise modelling of decarbonisation pathways (Section 16.2.4).

In addition to technological innovation, other innovation approaches are relevant in the context of climate mitigation and more broadly sustainable development (Section 16.6). Frugal innovations, that is, 'good enough' innovations that fulfil the needs of non-affluent consumers mostly in developing countries (Hossain 2018), are characterised by low costs, concentration on core functionalities, and optimised performance level (Weyrauch and Herstatt 2016) and are hence often associated with (ecological and social) sustainability (Albert 2019). Grassroots innovations are products, services and processes developed to address specific local challenges and opportunities, and which can generate novel, bottom-up solutions responding to local situations, interests and values. (Pellicer-Sifres et al. 2018; Dana et al. 2021).

16.2.1 Stages of the Innovation Process

The innovation cycle is commonly thought of as having three distinct innovation phases on the path between basic research and commercial application: Research and development (R&D); demonstration; and deployment and diffusion (IPCC 2007). Each of these phases differs with respect to the kind of activity carried out, the type of actors involved and their roles, financing needs, and the associated risks and uncertainties. All phases involve a process of trial and error, and failure is common; the share of innovation that successfully reaches the deployment phase is small. The path occurring between basic research and commercialisation is not linear (Section 16.3); it often requires a long time and is characterised by significant bottlenecks and roadblocks. Furthermore, technologies may regress in the innovation cycle, rather than move forward

(Skea et al. 2019). Successfully passing from each stage to the next one in the innovation cycle requires overcoming 'valleys of deaths' (Auerswald and Branscomb 2003; UNFCCC 2017), most notably the demonstration phase (Frank et al. 1996; Weyant 2011; Nemet et al. 2018). Over time, new and improved technologies are discovered; this often makes the dominant technology obsolete, but this is not discussed in this report.

Table 16.2 summarises the different innovation stages and main funding actors, and maps phases into the technology readiness levels (TRLs) discussed in Section 16.2.1.4.

16.2.1.1 Research and Development

This phase of the innovation process focuses on generating knowledge or solving particular problems by creating a combination of artefacts to perform a particular function, or to achieve a specific goal. R&D activities comprise basic research, applied research and technology development. Basic research is experimental or theoretical work undertaken primarily to acquire new knowledge of the underlying foundations of phenomena and observable facts, without any particular application or use in view. Applied research is original investigation undertaken in order to acquire new knowledge, primarily directed towards a specific, practical aim or objective (OECD 2015a). Importantly, R&D activities can be incremental – that is, focused on addressing a specific need by marginally improving an existing technology – or radical, representing a paradigm shift, promoted by new opportunities arising with the accumulation of new knowledge (Mendonça et al. 2018). Technology development, often leading to prototyping, consists of generating a working model of the technology that is usable in the real world, proving the usability and customer desirability of the technology, and giving an idea of its design, features and function (OECD 2015a). These early stages

Table 16.2 | Stages of the innovation process (Section 16.2.1) mapped onto technology readiness levels (Section 16.2.1.4). Source: adapted from Auerswald and Branscomb (2003), TEC (2017), IEA (2020a).

Stage	Main funding actors	Phases	Related technology readiness levels (TRLs)
Research and development	Governments Firms	Basic research	1 – Initial idea (basic principles defined)
		Applied research and technology development	2 – Application formulated (technology concept and application of solution formulated)
			3 – Concept needs validation (solutions need to be prototyped and applied)
			4 – Early prototype (prototype proven in test conditions)
			5 – Full prototype at scale (components proven in conditions to be deployed)
Demonstration	Governments Firms Venture Capital Angel investors	Experimental pilot project or full-scale testing	6 – Full prototype at scale (prototype proven at scale in conditions to be deployed)
			7 – Pre-commercial demonstration (solutions working in expected conditions)
			8 – First-of-a-kind commercial (commercial demonstration, full-scale deployment in final form)
			9 – Commercial operation in early environment (solution is commercial available, needs evolutionary improvement to stay competitive)
Deployment and diffusion	Firms Private equity Commercial banks Mutual funds International organisations and financial institutions Non-governmental organisations (NGOs)	Commercialisation and scale-up (<i>business</i>)	10 – Integration needed at scale (solution is commercial and competitive but needs further integration efforts)
		Transfer	11 – Proof of stability reached (predictable growth)

of technological innovation are referred to as the 'formative phase', during which the conditions are shaped for a technology to emerge and become established in the market (Wilson and Grubler 2013) and the constitutive elements of the innovation system emerging around a particular technology are set up (Bento and Wilson 2016; Bento et al. 2018) (Section 16.3).

The outcomes of R&D are uncertain: the amount of knowledge that will result from any given research project or investment is unknown *ex ante* (Rosenberg 1998). This risk to funders (Goldstein and Kearney 2020) translates into underinvestment in R&D due to low appropriability (Weyant 2011; Sagar and Majumdar 2014). In the case of climate mitigation technologies, low innovation incentives for the private sector also result from a negative environmental externality (Jaffe et al. 2005). Furthermore, in the absence of stringent climate policies and targets, incumbent fossil-based energy technologies are characterised by lower financing risk, are heavily subsidised (Davis 2014; Kotchen 2021), and depreciate slowly (Arrow 1962a; Nanda et al. 2016; Semieniuk et al. 2021) (Section 16.2.3). In this context, public research funding plays a key role in supporting high-risk R&D, both in developed and developing economies: it can provide patient and steady funding not tied to short-term investment returns (Kammen and Nemet 2007; Anadon et al. 2014; Mazzucato 2015a; Chan and Diaz Anadon 2016; Anadon et al. 2017; Howell 2017; Zhang et al. 2019) (Section 16.4). Public policies also play a role in increasing private incentives in energy research and development funding (Nemet 2013). R&D statistics are an important indicator of innovation and are collected following the rules of the *Frascati Manual* (OECD 2015a) (Section 16.3.3, Box 16.3 and Table 16.7).

16.2.1.2 Demonstration

Demonstration is carried out through pilot projects or large-scale testing in the real world. Successfully demonstrating a technology shows its utility and that it is able to achieve its intended purpose and, consequently, that the risk of failure is reduced (i.e., that it has market potential) (Hellsmark et al. 2016). Demonstration projects are an important step to promote the deployment of low-carbon energy and industrial technologies in the context of the transition. Government funding often plays a large role in energy technology demonstration projects because scaling up hardware energy technologies is expensive and risky (Brown and Hendry 2009; Hellsmark et al. 2016). Governments' engagement in low-carbon technology demonstration also signals support for businesses willing to take the investment risk (Mazzucato 2016). Venture capital, traditionally not tailored for energy investment, can also play an increasingly important role, thanks to the incentives (e.g., through de-risking) provided by public funding and policies (Gaddy et al. 2017; IEA 2017a).

16.2.1.3 Deployment and Diffusion

Deployment entails producing a technology at large scale and scaling up its adoption and use across individual firms or households in a given market, and across different markets (Jaffe 2015). In the context of climate change mitigation and adaptation technologies, the purposeful diffusion to developing countries, is referred to as 'technology transfer'. Most recently, the term 'innovation cooperation' has been proposed

to indicate that technologies need to be co-developed and adapted to local contexts (Pandey et al. 2021). Innovation cooperation is an important component of stringent mitigation strategies as well as international agreements (Section 16.5).

Diffusion is often sluggish due to lock-in of dominant technologies (Liebowitz and Margolis 1995; Unruh 2000; Ivanova et al. 2018), as well as the time needed to diffuse information about the technologies, heterogeneity among adopters, the incentive to wait until costs fall even further, the presence of behavioural and institutional barriers, and the uncertainty surrounding mitigation policies and long-term commitments to climate targets (Gillingham and Sweeney 2012; Corey 2014; Jaffe 2015; Haelg et al. 2018). In addition, novel technology has been hindered by the actions of powerful incumbents who accrue economic and political advantages over time, as in the case of renewable energy generation (Unruh 2002; Supran and Oreskes 2017; Hoppmann et al. 2019).

Technologies have been shown to penetrate the market with a gradual non-linear process in a characteristic logistic (S-shaped) curve (Grubler 1996; Rogers 2003). The time needed to reach widespread adoption varies greatly across technologies relevant for adaptation and mitigation (Gross et al. 2018); in the case of energy technologies, the time needed for technologies to get from a 10–90% market share of saturation ranges between 5 to over 70 years (Wilson 2012). Investment in commercialisation of low-emission technology is largely provided by private financiers; however, governments play a key role in ensuring incentives through supportive policies, including R&D expenditures providing signals to private investors (Haelg et al. 2018), pricing carbon dioxide emissions, public procurement, technology standards, information diffusion and the regulation for end-lifecycle treatment of products (Cross and Murray 2018) (Section 16.4).

16.2.1.4 Technology Readiness Levels

Technology readiness levels (TRLs) are a categorisation that enables consistent, uniform discussions of technical maturity across different types of technology. They were developed by the National Aeronautics and Space Administration (NASA) in the 1970s (Mankins 1995, 2009) and originally used to describe the readiness of components forming part of a technological system. Over time, more classifications of TRLs have been introduced, notably the one used by the European Union (EU). Most recently, the International Energy Agency (IEA) extended previous classifications to include the later stages of the innovation process (IEA 2020b) and applied it to compare the market readiness of clean energy technologies and their components (OECD 2015a; IEA 2020b). TRLs are currently widely used by engineers, business people, research funders and investors, often to assess the readiness of whole technologies rather than single components. To determine a TRL for a given technology, a technology readiness assessment (TRA) is carried out to examine programme concepts, technology requirements, and demonstrated technology capabilities. In the most recent version of the IEA (IEA 2020b), TRLs range from 1 to 11, with 11 indicating the most mature (Table 16.2).

The purpose of TRLs is to support decision-making. They are applied to avoid the premature application of technologies, which would lead

to increased costs and project schedule extensions (US Department of Energy 2011). They are used for risk management, and can also be used to make decisions regarding technology funding, and to support the management of the R&D process within a given organisation or country (De Rose et al. 2017).

In practice, the usefulness of TRLs is limited by several factors. These include limited applicability in complex technologies or systems, the fact that they do not define obsolescence, nor account for manufacturability, commercialisation or the readiness of organisations to implement innovations (European Association of Research Technology Organisations 2014) and do not consider any type of technology-system mismatch or the relevance of the products' operation environment to the system under consideration (Mankins 2009). Many of these limitations can be eased by using TRLs in combination with other indicators such as system readiness levels and other economic indicators on, for example, investments and returns (IEA 2020b).

16.2.2 Sources of Technological Change

The speed of technological change could be explained with the key drivers of innovations process: R&D effort; learning by doing; and spillover effects. In addition, new innovations are sometimes enabled by the development of general purpose technologies, such as digitalisation.

16.2.2.1 Learning by Doing and Research and Development

Learning by doing and R&D efforts are two factors commonly used by the literature to explain past and projected future speed of technological change (Klaassen et al. 2005; Mayer et al. 2012; Bettencourt et al. 2013). Learning by doing is the interaction of workers with new machines or processes that allows more efficient use (Arrow 1962b). R&D effort is dedicated to looking for new solutions (e.g., blueprints) that could increase the efficiency of existing production methods or result in entirely new methods, products or services (Section 16.2.1.1).

Learning by doing and R&D are interdependent. Young (1993) postulates that learning by doing cannot continue forever without R&D because it is bounded by an upper physical productivity limit of an existing technology. R&D can shift this limit because it allows for replacing the existing technology with a new one. On the other hand, incentives to invest in R&D depend on the future cost of manufacturing, which in turn depends on the scale of learning by doing. The empirical evidence for virtuous circle between cost reduction, market growth and R&D were found in the case of the photovoltaic (PV) market (Watanabe et al. 2000) (Box 16.4), but could also lead to path dependency and lock-in (Erickson et al. 2015). Sections 16.4.4 and 13.7.3.1 discuss how simultaneous use of technology push and pull policies could amplify the effects of research and learning.

The benefits of R&D and learning by doing are larger at the economy level than at the firm level (Arrow 1962b; Romer 1990;). As a result, when left to its own, the market tends to generate less investment than socially optimal. For instance, if the cost of a technology is too high before a large amount of learning by doing has occurred, there is a risk that it will not be adopted by the market, even if it is economically advantageous for the society. Indeed, initially new technologies are often expensive and cannot compete with the incumbent technologies (Cowan 1990). Large numbers of adopters could lower this cost via learning by doing to a level sufficient to beat the incumbent technology (Gruebler et al. 2012). However, firms could hesitate to be the first adopter and bear the high cost (Isoard and Soria 2001). If this disadvantage overwhelms the advantages of being a first mover¹ and if adopters are not able to coordinate, it will lead to situation of a lock-in (Gruebler et al. 2012).

The failure of markets to deliver the size of R&D investment and learning by doing that would be socially optimal is one of the justifications of government intervention. Policies to address these market failures can be categorised as technology-push and demand-pull policies. The role of these policies is explained in Table 16.3.

Section 16.4 discusses individual policy instruments in greater detail.

Table 16.3 | Categories of policies and interventions accelerating technological changes, the factors promoting them and slowing them down, illustrated with examples.

	What it refers to	What promotes technological change	What slows down technological change	Examples
Technology push	Support the creation of new knowledge to make it easier to invest in innovation	Research and development (R&D), funding and performance of early demonstrations (Brown and Hendry 2009; Hellsmark et al. 2016)	Inadequate supply of trained scientists and engineers (Popp and Newell 2012); gap with demand pull (Grübler et al. 1999b)	Japan's Project Sunshine, the US Project Independence in the 1970s. Breakthrough Energy Coalition and Mission Innovation, respectively private- and public-sector international collaborations to respectively focus energy innovation and double energy R&D, both initiated concurrently with the Paris Agreement in 2015 (Sanchez and Sivaram 2017)
Demand pull	Instruments creating market opportunities	Enlarging potential markets, increasing adoption of new fuels and mitigation technology Digital innovations Social innovation and awareness	Willingness of consumers to accept new technology Policy and political volatility can deter investment	Subsidies for wind power California, the German feed-in tariff for photovoltaic, quotas for electric vehicles in China (F. Wang et al. 2017) and Norway (Pereirinha et al. 2018) Biofuels (Brazil) Social innovation with wind energy (Denmark, Germany)

¹ For example, see Spence (1981) and Bhattacharya (1984) for a discussion of first-mover advantages.

The size of the learning-by-doing effect is quantified in literature using learning rates, that is estimates of negative correlation between costs and size of deployment of technologies. The results from this literature include estimates for energy technologies (McDonald and Schrattenholzer 2001), electricity generation technologies (Rubin et al. 2015; Samadi 2018), for storage (Schmidt 2017), for end-of-pipe control (Kang et al. 2020) and for energy demand and energy supply technologies (Weiss et al. 2010). Meta-analyses find that learning rates vary across technologies, within technologies, and over time (Nemet 2009a; Rubin et al. 2015; Wei et al. 2017). Moreover, different components of one technology have different learning rates (Elshurafa et al. 2018). Central tendencies are around 20% cost reduction for each doubling of deployment (McDonald and Schrattenholzer 2001).

Studies of correlation between cumulative deployment of technologies and costs are not sufficiently precise to disentangle the causal effect of increase in deployment from the causal effects of R&D and other factors (Nemet 2006). Numerous subsequent studies attempted to, among others issues, separate the effect of learning by doing and R&D (Klaassen et al. 2005; Mayer et al. 2012; Bettencourt et al. 2013), economies of scale (Arce 2014), and knowledge spillovers (Nemet 2012). Once those other factors are accounted for, some empirical studies find that the role of learning by doing in driving down the costs becomes minor (Nemet 2006; Kavlak et al. 2018). In addition, the relation could reflect reverse causality: increase in deployment could be an effect (and not a cause) of a drop in price (Nordhaus 2014; Witajewski-Baltvilks et al. 2015). Nevertheless, in some applications, learning curves can be a useful proxy and heuristic (Nagy et al. 2013).

The negative relation between costs and experience is a reason to invest in a narrow set of technologies; the uncertainty regarding the parameters of this relation is the reason to invest in wider ranges of technologies (Fleming and Sorenson 2001; Way et al. 2019). Concentrating investment in narrow sets of technologies (specialisation) enables fast accumulation of experience for these technologies and large cost reductions. However, when the potency of technology is uncertain, one does not know which technology is truly optimal in the long run. The narrower the set, the higher the risk that the optimal technology will not be supported, and hence will not benefit from learning by doing. Widening the set of supported technologies would reduce this risk (Way et al. 2019). Uncertainty is present because noise in historical data hides the true value of learning rates, and due to unanticipated future shocks to technology costs (Lafond et al. 2018). Ignoring uncertainty in integrated assessment models implies that these model results are biased towards supporting a narrow set of technologies, neglecting the benefits of decreasing risk through diversification (Sawulski and Witajewski-Baltvilks 2020).

16.2.2.2 Knowledge Spillovers

Knowledge spillovers drive continuous technological change (Romer 1990; Rivera-Batiz and Romer 1991) and are for that reason relevant to climate technologies as well as incumbent, carbon-intensive technologies. Knowledge embedded in innovations by one innovator

gives an opportunity for others to create new innovations and increase the knowledge stock even further. The constant growth of knowledge stock through spillovers translates into constant growth of productivity and cost reduction.

By allowing for experimenting with existing knowledge and combining different technologies, knowledge spillovers can result in the emergence of novel technological solutions, which has been referred to as 'recombinant innovation' (Weitzman 1998; Fleming and Sorenson 2001; Olsson and Frey 2002; Tsur and Zemel 2007; Arthur 2009). Recombinant innovations speed up technological change by combining different technological solutions, and make things happen that would be impossible with only incremental innovations (van den Bergh 2008; Safarzyńska and van den Bergh 2010; Frenken et al. 2012). It has been shown that 77% of all patents granted between 1790 and 2010 in the USA are coded by a combination of at least two technology codes (Youn et al. 2015). Spillovers related to energy and low-carbon technologies have been documented by a number of empirical studies (*high confidence*) (Popp 2002; Verdolini and Galeotti 2011; Aghion et al. 2016; Witajewski-Baltvilks et al. 2017; Conti et al. 2018). The presence of spillovers can have both positive and negative impacts on climate change mitigation (*high confidence*).

The spillover effect associated with innovation in carbon-intensive technologies may lead to lock-in of fossil-fuel technologies. Continuous technological change of carbon-intensive industry raises the bar for clean technologies: a larger drop in clean technologies' cost is necessary to become competitive (Acemoglu et al. 2012; Aghion et al. 2016). The implication is that delaying climate policy increases the cost of that policy (Aghion 2019).

On the other hand, the spillover effect associated with innovation in low-emission technologies increases the potency of climate policy (Aghion 2019). For instance, a policy that encourages clean innovation leads to accumulation of knowledge in clean industry which, through spillover effects, encourages further innovation in clean industries. Once the stock of knowledge is sufficiently large, the value of clean industries will be so high that technology firms will invest there, even without policy incentives. Once this point is reached, the policy intervention can be discontinued (Acemoglu et al. 2012).

In addition, the presence of spillovers implies that a unilateral effort to reduce emissions in one region could reduce emissions in other regions (*medium confidence*) (Golombek and Hoel 2004; Gerlagh and Kuik 2014). For instance, in the presence of spillovers, a carbon tax that incentivises clean technological change increases the competitiveness of clean technologies not only locally, but also abroad. The size of this effect depends on the size of the spillovers. If they are sufficiently strong, the reduction of emissions abroad due to clean technological change could be larger than the increase of emissions due to carbon leakage (Gerlagh and Kuik 2014). Different types of carbon leakage are discussed in Chapter 13, Section 13.7.1, and other consequences of spillovers for the design of policy are discussed in Chapter 13, Section 13.7.3.

16.2.2.3 General-purpose Technologies and Digitalisation

General-purpose technologies (GPTs) provide solutions that could be applied across sectors and industries (Goldfarb 2011) by creating technological platforms for a growing number of interrelated innovations. Examples of GPTs relevant to climate change mitigation are hydrogen and fuel cell technology, which may find applications in transport, industry and distributed generation (Hanley et al. 2018), and nanotechnology which played a significant role in advancement of all the different types of renewable energy options (Hussein 2015). Assessing the environmental, social and economic implications of such technologies, including increased emissions through energy use, is challenging (Section 5.3.4.1 and Cross-Chapter Box 11 in this chapter).

Several GPTs relevant for climate mitigation and adaptation emerged as a result of digitalisation, namely the adoption or increase in the use of information and communication technologies (ICTs) by citizens, organisations, industries or countries, and the associated restructuring of several domains of social life and of the economy around digital technologies and infrastructures (Brennen and Kreiss 2016; IEA 2017b). The digital revolution is underpinned by innovation in key technologies, for example, ubiquitous connected consumer devices such as mobile phones (Grubler et al. 2018), rapid expansions of global internet infrastructure and access (World Bank 2014), and steep cost reductions and performance improvements in computing devices, sensors, and digital communication technologies (Verma et al. 2020). The increasing pace at which the physical and

digital worlds are converging increases the relevance of disruptive digitalisation in the context of climate mitigation and sustainability challenges (European Commission 2020) (Cross-Chapter Box 11 in this chapter and Chapter 4, Section 4.4.1).

Digital technologies require energy, but increase efficiency, potentially offering technology-specific greenhouse gas (GHG) emission savings; they also have larger system-wide impacts (Kaack et al. 2021). In industrial sectors, robotisation, smart manufacturing (SM), internet of things (IoT), artificial intelligence (AI), and additive manufacturing (AM or 3D printing) have the potential to reduce material demand and promote energy management (Section 11.3.4.2). Smart mobility is changing transport demand and efficiency (Section 10.2.3). Smart devices in buildings, the deployment of smart grids and the provision of renewable energy increase the role of demand-side management (Serrenho and Bertoldi 2019) (Sections 9.4 and 9.5), and support the shift away from asset redundancy (Section 6.4.3). Digital solutions are equally important on the supply side, for example, by accelerating innovation with simulations and deep learning (Rolnick et al. 2021) or realising flexible and decentralised opportunities through energy-as-a-service concepts and particularly with pay-as-you-go (Section 15.6.8).

Yet, increased digitalisation could increase energy demand, thus wiping away potential efficiency benefits, unless appropriately governed (IPCC 2018a). Moreover, digital technologies could negatively impact labour demand and increase inequality (Cross-Chapter Box 11 in this chapter).

Cross-Chapter Box 11 | Digitalisation: Efficiency Potentials and Governance Considerations

Authors: Felix Creutzig (Germany), Elena Verdolini (Italy), Paolo Bertoldi (Italy), Luisa F. Cabeza (Spain), María Josefina Figueroa Meza (Venezuela/Denmark), Kirsten Halsnæs (Denmark), Joni Jupesta (Indonesia/Japan), Şiir Kilkiş (Turkey), Michael König (Germany), Eric Masanet (the United States of America), Nikola Milojevic-Dupont (France), Joyashree Roy (India/Thailand), Ayyoob Sharifi (Iran/Japan)

Digital technologies impact positively and negatively on GHG emissions through: their own carbon footprint; technology application for mitigation; and induced larger social change. Digital technologies also raise broader sustainability concerns due to their use of rare materials and associated waste, and their potential negative impact on inequalities and labour demand.

Direct impacts emerge because digital technologies consume large amounts of energy, but also have the potential to steeply increase energy efficiency in all end-use sectors through material input savings and increased coordination (medium evidence, medium agreement) (Horner et al. 2016; Huang et al. 2016; IEA 2017b; Jones 2018). Global energy demand from digital appliances reached 7.14 EJ in 2018 (Chapter 9, Box 9.5), implying higher related carbon emissions. However, a small smartphone offers services previously requiring many different devices (Grubler et al. 2018). Demand for data services is increasing rapidly; quantitative estimates of the growth of associated energy demand range from slow and marginal to rapid and sizeable, depending the efficiency trends of digital technologies (Avgerinou et al. 2017; Vranken 2017; Stoll et al. 2019; Masanet et al. 2020) (Section 5.3.4.1). Renewable energy can serve as a low-carbon energy provider for the operation of a data centre, which in turn can provide waste heat for other purposes. Digital technologies can markedly increase the energy efficiency of mobility and residential and public buildings, especially in the context of systems integration (IEA 2020a). Reduction in energy demand and associated GHG emissions from buildings and industry, while maintaining service levels is estimated at 5 to 10%, with larger savings possible. Approaches include building energy management systems (BEMS), home energy management system (HEMS), demand response

Cross-Chapter Box 11 (continued)

and smart charging (Cross-Chapter Box 11, Table 1). Data centres can also play a role in energy system management, for example, by increasing renewable energy generation through predictive control (Dabbagh et al. 2019), and by helping to drive the market for battery storage and fuel cells (Riekstin et al. 2014). Temporal and spatial scheduling of electricity demand can provide about 10 GW in demand response in the European electricity system in 2030 (Wahlroos et al. 2017, 2018; Koronen et al. 2020; Laine et al. 2020).

However, system-wide effects may endanger energy and GHG emission savings (*high evidence, high agreement*). Economic growth resulting from higher energy and labour productivities can increase energy demand (Lange et al. 2020) and associated GHG emissions. Importantly, digitalisation can also benefit carbon-intensive technologies (Victor 2018). Impacts on GHG emissions are varied in smart and shared mobility systems, as ride hailing increases GHG emissions due to deadheading, whereas shared pooled mobility and shared cycling reduce GHG emissions, as occupancy levels and/or weight per person km transported improve (Section 5.3). Energy and GHG emission impacts from the ubiquitous deployment of smart sensors and service optimisation applications in smart cities are insufficiently assessed in the literature (Milojevic-Dupont and Creutzig 2021). Systemic effects have wider boundaries of analysis, including broader environmental impacts (e.g., demand for rare materials, disposal of digital devices). These need to be

Cross-Chapter Box 11, Table 1 | Selected sector approaches for reducing GHG emissions that are supported by new digital technologies. Contributions of digitalisation include a) supporting role (+), b) necessary role in mix of tools (++), c) necessary unique contribution (+++), but digitalisation may also increase emissions (–). (Chapters 5, 8, 9 and 11).

Sector	Approach	Quantitative evidence	Contribution of digitalisation	Systems perspective and broader societal impacts	References
Residential energy use	Nudges (feedback, information, etc.)	2–4% reduction in global household energy use possible	+ In combination with monetary incentives, non-digital information	New appliances increase consumption	Zangheri et al. (2019); Buckley (2020); Nawaz et al. (2020); Khanna et al. (2021)
Smart mobility	Shared mobility and digital feedback (ecodriving)	Reduction for shared cycling and shared pooled mobility; increase for ride hailing/ ride sourcing; reduction for eco-driving	– or ++ Apps together with big data and machine learning algorithm key precondition for new shared mobility	Ride hailing increases GHG emissions, especially due to deadheading	Zeng et al. (2017); OECD and ITF (2020)
Smart cities	Using digital devices and big data to make urban transport and building use more efficient	Precise data about roadway use can reduce material intensity and associated GHG emissions by 90%	++ Big data analysis necessary for optimisation	Efficiency gains are often compensated by more driving and other rebound effects; privacy concerns linked with digital devices in homes	Milojevic-Dupont and Creutzig (2021) (Chapter 10, Box 10.1)
Agriculture	Precision agriculture through sensors and satellites providing information on soil moisture, temperature, crop growth and livestock feed levels	Very high potential for variable-rate nitrogen application, moderate potential for variable-rate irrigation	+ ICTs provide information and technologies which enables farmers to increase yields, optimise crop management, reduce fertilisers and pesticides, feed and water; increases efficiency of labour-intensive tasks	The digital divide is growing fast, especially between modern and subsistence farming; Privacy and data may erode trust in technologies	Deichmann et al. (2016); Chlingaryan et al. (2018); Soto Embodas et al. (2019); Townsend et al. (2019)
Industry	Industrial internet of things (IIoT)	Process, activity and functional optimisation increases energy and carbon efficiency	++ Increased efficiency ++ 1.3 GtCO ₂ -eq estimated abatement potential in manufacturing + Promote sustainable business models	Optimisation in value chains can reduce wasted resources	GeSI (2012); Wang et al. (2016); Parida et al. (2019); Rolnick et al. (2021)
Load management and battery storage optimisation	Big data analysis for optimising demand management and using flexible load of appliances with batteries	Reduces capacity intended for peak demand, shifts demand to align with intermittent renewable energy availability	+ Accelerated experimentation in material science with artificial intelligence ++ / +++ Forecast and control algorithms for storage and dispatch management	Facilitate integration of renewable energy sources Improve utilisation of generation assets System-wide rebound effects possible	Akorede et al. (2010); Aghaei and Alizadeh (2013); de Sisternes et al. (2016); Voyant et al. (2017); Gür (2018); Hirsch et al. (2018); Sivaram (2018a); Vázquez-Canteli and Nagy (2019) (Chapter 6, Section 6.4)

Cross-Chapter Box 11 (continued)

integrated holistically within policy design (Kunkel and Matthess 2020), but they are difficult to quantify and investigate (Bieser and Hilty 2018). Policies and adequate infrastructures and choice architectures can help manage and contain the negative repercussions of systemic effects (Sections 5.4, 5.6 and 9.9).

Broader societal impacts of digitalisation can also influence climate mitigation because of induced demand for consumption goods, impacts on firms' competitiveness, changes the demand for skills and labour, worsening of inequality – including reduced access to services due to the digital divide – and governance aspects (*low evidence, medium agreement*) (Sections 4.4, 5.3 and 5.6). Digital technologies expand production possibilities in sectors other than ICTs through robotics, smart manufacturing, and 3D printing, and have major implications on consumption patterns (Matthess and Kunkel 2020). Initial evidence suggests that robots displace routine jobs and certain skills, change the demand for high-skilled and low-skilled workers, and suppress wages (Acemoglu and Restrepo 2019). Digitalisation can thus reduce consumers' liquidity and consumption (Mian et al. 2020) and contribute to global inequality, including across the gender dimension, raising fairness concerns (Kerras et al. 2020; Vassilakopoulou and Hustad 2021). Digital technologies can lead to additional concentration in economic power (e.g., Rikap 2020) and lower competition; however, open source digital technologies can counter this tendency (e.g., Rotz et al. 2019). Digital technologies play a role in mobilising citizens for climate and sustainability actions (Seegerberg 2017; Westerhoff et al. 2018).

Whether the digital revolution will be an enabler or a barrier for decarbonisation will ultimately depend on the governance of both digital decarbonisation pathways and digitalisation in general (*medium evidence, high agreement*). The understanding of the disruptive potential of the wide range of digital technologies is limited due to their ground-breaking nature, which makes it hard to extrapolate from previous history/experience. Municipal and national entities can make use of digital technologies to manage and govern energy use and GHG emissions in their jurisdiction (Bibri 2019a,b) and break down solution strategies to specific infrastructures, building, and places, relying on remote sensing and mapping data, and contextual machine learning about their use (Milojevic-Dupont and Creutzig 2021). Mobility apps can provide mobility-as-a-service access to cities, ensuring due preference to active and healthy modes (Section 9.9 for the example of the Finnish city of Lahti). Trusted data governance can promote the implementation of local climate solutions, supported by available big data on infrastructures and environmental quality (Hansen and Porter 2017; Hughes et al. 2020). Governance decisions, such as taxing data, prohibiting surveillance technologies, or releasing data that enable accountability, can change digitalisation pathways, and thus underlying GHG emission (Hughes et al. 2020).

Closing the digital gap in developing countries and rural communities enables an opportunity for leapfrogging (*medium evidence, medium agreement*). Communication technologies (such as mobile phones) enable the participation of rural communities, especially in developing countries, and promote technological leapfrogging, for example, decentralised renewable energies and smart farming (Ugur and Mitra 2017; Foster and Azmeh 2020; Arfanuzzaman 2021). Digital technologies have sector-specific potentials and barriers, and may benefit certain regions/areas/socio-economic groups more than others. For example, integrated mobility services benefit cities more than rural and peripheral areas (OECD 2017).

Appropriate mechanisms also need to be designed to govern digitalisation as a megatrend (*medium evidence, high agreement*). Digitalisation is expected to be a fast process, but this transformation takes place against entrenched individual behaviours, existing infrastructure, the legacy of time frames, vested interest and slow institutional processes, and requires trust from consumers, producers and institutions. A core question relates to who controls and manages data created by everyday operations (calls, shopping, weather data, service use, and so on). Regulations that limit or ban the expropriation and exploitation of behavioural data, sourced via smartphones, represent crucial aspects in digitalisation pathways, alongside the possibility to create climate movements and political pressure from the civil society. Governance mechanisms need to be developed to ensure that digital technologies such as AI take over ethical choices (Craglia et al. 2018; Rahwan et al. 2019). Appropriate governance is necessary for digitalisation to effectively work in tandem with established mitigation technologies and choice architectures. Consideration of system-wide effects and overall management is essential to avoid runaway effects. Overall governance of digitalisation remains a challenge, and will have large-scale repercussions on energy demand and GHG emissions.

16.2.2.4 Explaining Past and Projecting Future Technology Cost Changes

Researchers and policymakers alike are interested in using observed empirical patterns of learning to project future reductions in costs of technologies. Studies cutting across a wide range of industrial sectors (not just energy) have tried to relate cost reductions to different functional forms, including cost reductions as a function of time (Moore's law) and cost reductions as a function of production or deployment (Wright's law, also known as Henderson's law), finding that those two forms perform better than alternatives combining different factors, with costs as a function of production (Wright's law) performing marginally better (Nagy et al. 2013). A comparison of expert elicitation and model-based forecasts of the future cost of technologies for the energy transition indicates that model-based forecast medians were closer to the average realised values in 2019 (Meng et al. 2021).

Recent studies attempt to separate the influence of learning by doing (which is a basis of Wright's law) versus other factors in explaining cost reductions, specifically in energy technologies. Some studies explain cost reductions with two factors: cumulative deployment (as proxy for experience); and R&D investment – see the 'two factor' learning curve (Klaassen et al. 2005). However, reliable information on public energy R&D investments for developing countries is not systematically collected. Available data for OECD countries cannot be precisely assigned to specific industrial sectors or sub-technologies (Verdolini et al. 2018). Some learning-curve studies take into account that historical variation in technology costs could be explained by variation in key materials and fuel costs – for example, steel costs for wind turbines (Qiu and Anadon 2012), silicon costs (Nemet 2006; Kavlak et al. 2018) as well as coal and coal plant construction costs (McNerney et al. 2011). Economies of scale played a significant role in the PV cost reductions since the early 2000s (Yu et al. 2011) (Box 16.4), which can also become the case in organic PV technologies (Gambhir et al. 2016; Kavlak et al. 2018).

16.2.3 Directing Technological Change

Technological change is characterised not only by its speed, but also its direction. The early works that considered the role of technology in economic and productivity growth (Solow 1957; Nelson and Phelps 1966) assumed that technology can move forward along only one dimension – every improvement led to an increase in efficiency and increased demand for all factors of production. This view, however, ignores the potency of technological change to alter the otherwise fixed relation between economic growth and the use of resources.

Technological change that saves fossil fuels could decouple economic growth and CO₂ emissions (Acemoglu et al. 2012, 2014; Hémous 2016; Grecker et al. 2018). Saving of fossils could be obtained with increasing efficiency of producing alternatives to fossils (Acemoglu et al. 2012, 2014). This is the case of oil consumption by combustion engine cars which could be substituted with electric cars (Aghion et al. 2016). If there is no close substitute for a 'dirty resource', then its intensity in production could still be reduced by increasing the

efficiency of the dirty resource relative to the efficiency of other inputs (Hassler et al. 2012; André and Smulders 2014; Witajewski-Baltvilks et al. 2017). For instance, energy efficiency improvement leads to a drop in relative demand for energy (Hassler et al. 2012; Witajewski-Baltvilks et al. 2017).

16.2.3.1 Determinants of Technological Change Direction: Prices, Market Size and Government

Firms change their choice of technology upon change in prices: when one input (e.g., energy) becomes relatively expensive, firms pick technologies that allow them to economise on that input, according to price-induced technological change theory (Reder and Hicks 1965; Samuelson 1965; Sue Wing 2006). For example, an increase in oil price will lead to a choice of fuel-saving technologies. Such a response of technological change was evident during the oil-price shocks in the 1970s (Hassler et al. 2012). Technological change that is induced by an increase in price of a resource can never lead to an increase in use of that resource. In other words, rebound effects associated with induced technological change can never offset the saving effect of that technological change (Antosiewicz and Witajewski-Baltvilks 2021).

The impact of energy prices on the size of low-carbon technological change is supported by large number of empirical studies (Popp 2019; Grubb and Wieners 2020). Studies document that higher energy prices are associated with a higher number of low-carbon energy or energy efficiency patents (Newell et al. 1999; Popp 2002; Verdolini and Galeotti 2011; Noailly and Smeets 2015; Ley et al. 2016; Witajewski-Baltvilks et al. 2017; Lin and Chen 2019). Sue Wing (2008) finds that innovation induced by energy prices had a minor impact on the decline in US energy intensity in the last decades of the 20th century, and that autonomous technological change played a more important role. Several studies explore the impact of a carbon tax on green innovation (Section 16.4). However, disentangling the effect of policy tools is complex because the presence of some policies could distort the functioning of other policies (Böhringer and Rosendahl 2010; Fischer et al. 2017) and because the impact of policies could be lagged in time (Antosiewicz and Witajewski-Baltvilks 2021).

The direction of technological change depends also on the market size for dirty technologies relative to the size of other markets (Acemoglu et al. 2014). Due to this dependence, climate and trade policy choices in a single region can alter the direction of technological change at the global level (Section 16.2.3.3).

The value of the market for clean technologies is determined not only by current profit, but also by a firm's expectation of future profits (Alkemade and Suurs 2012; Grecker et al. 2018; Aghion 2019). One implication is that bolstering the credibility and durability of policies related to low-carbon technology is crucial to accelerating technological change and inducing the private sector investment required (Helm et al. 2003), especially in the rapidly growing economies of Asia and Africa which are on the brink of making major decisions about the type of infrastructure they build as they grow, develop, and industrialise (Nemet et al. 2017).

If governments commit to climate policies, firms expect that the future size of markets for clean technologies will be large and they are eager to redirect research effort towards development of these technologies today. The commitment would also incentivise acquiring skills that could further reduce the costs of those technologies (Aghion 2019). However, historical evidence shows that policies related to energy and climate over the long term have tended to change (Taylor 2012; Nemet et al. 2013; Koch et al. 2016). Still, where enhancing policy durability has proven infeasible, multiple uncorrelated potentially overlapping policies can provide sufficient incentives (Nemet 2010).

16.2.3.2 Determinants of Direction of Technological Change: Financial Markets

The challenges of investing in innovation in energy when compared to other important areas, such as ICT and medicine are also reflected in the trends in venture capital funding. Research found that early-stage investments in cleantech companies were more likely to fail and returned less capital than comparable investments in software and medical technology (Gaddy et al. 2017). This led to investors retreating from hardware technologies required for renewable energy generation and storage, and moving to software-based technologies and demand-side solutions (Bumpus and Comello 2017).

The preference for particular types of investments in renewable energy technologies depends on investors attitude to risk (Mazzucato and Semieniuk 2018). Some investors invest in only one technology, others may spread their investments, or invest predominantly in high-risk technologies. The distribution of different types of investors will affect whether finance goes to support deployment of new high-risk technologies, or diffusion of more mature, less-risky technologies characterised by incremental innovations. The role of finance in directing investment is further discussed in Chapter 15, Section 15.6.2.

16.2.3.3 Internationalisation of Green Technological Change

A unilateral effort to reduce emissions (via a combination of climate, industrial and trade policies) in a coalition of regions that are technology leaders will reduce the cost of clean technologies, and induce emissions reduction in the countries outside the coalition (Golombek and Hoel 2004; Di Maria and Smulders 2005; Di Maria and van der Werf 2008; Hémous 2016; van den Bijgaart 2017). The literature suggests various mechanisms leading to this result. Di Maria and van der Werf (2008) argue that the effort to reduce emissions in one region reduces global demand for 'dirty goods'. This will redirect global innovation towards clean technologies, leading to a drop in the cost of clean production in every region.

The model in Hemous (2016) predicts that such a coalition could induce acceleration of clean technological change through a mix of carbon taxation, clean R&D subsidies and trade policies in that region leading to reduction of cost of clean production inside the coalition. Export of goods produced with clean technologies to a region outside the coalition reduces demand for dirty goods in that region. In the model by van den Bijgaart (2017) local advancements of clean technologies by a coalition with strong R&D potential are imitated outside the coalition. Furthermore, advancements of clean technologies will incentivise future clean R&D outside the coalition due to intertemporal knowledge spillovers. In Golombek and Hoel (2004) an increase in environmental concern in one region increases abatement R&D in that region. Part of this knowledge spills over to other regions, increasing their incentive to increase abatement too, provided that the latter regions did not invest in abatement before.

However, this chain breaks if the regions that are behind the technological frontier (i.e., technological followers) are not able to absorb the solutions developed by regions at the frontier. New technologies might fail due to deficiencies of political, commercial, industrial, and financial institutions, which we list in Table 16.4. For instance, countries might not benefit fully from international knowledge spillovers due to insufficient domestic R&D investment, since local knowledge is needed to determine the appropriateness of technologies for the local market, adapting them, installing and using effectively (Gruebler et al. 2012). From the policy perspective, this implies that simple transfer of technologies could be insufficient to guarantee adoption of new technologies (Gruebler et al. 2012).

Research relying on patent citations has indicated that Foreign Direct Investment (FDI) is a mechanism for firms to contribute to the recipient country's innovation output as well as benefit from the recipient country in industrialised countries (Branstetter 2006) and in developing countries (Newman et al. 2015). However, insights specific for energy or climate change mitigation areas are not available, nor is there much information about how other innovation metrics may react to FDI.

Finally, technologies could be not efficient in developing countries, even if they are efficient in countries at the technological frontier. For instance, technologies that are highly capital intensive and labour saving will be efficient only in countries where costs of capital are low and costs of labour are high. Similarly, technologies which require a large number of skilled labour will be more competitive in a country where skilled labour is abundant (and hence cheap) than where it is scarce (Basu and Weil 1998; Caselli and Coleman 2006).

Table 16.4 | Examples of institutional deficiencies preventing deployment of new technologies in countries behind the technological frontier.

Institutions	Examples of deficiencies	Literature reference
Industrial	Inability to benefit fully from international knowledge spillover due to insufficient domestic R&D investment	Mancusi (2008); Unel (2008); Gruebler et al. (2012)
Commercial	Insufficient experience with the organisation and management of large-scale enterprise	Abramovitz (1986); Aghion et al. (2005)
Political	Vested interests and customary relations among firms and between employers and employees	Olson (1982); Abramovitz (1986)
Financial	Financial markets incapable of mobilising capital for individual firms at large scale	Abramovitz (1986); Aghion et al. (2005)

16.2.3.4 Market Failures in Directing Technological Change

Market forces alone cannot deliver Pareto optimal (i.e., social) efficiency due to at least two types of externalities: GHG emissions that cause climate damage; and knowledge spillovers that benefit firms other than the inventor. Nordhaus (2011) argues that these two problems would have to be tackled separately: once the favourable intellectual property right regimes (i.e., the laws or rules or regulation on protection and enforcement) are in place, a price on carbon that corrects the emission externality is sufficient to induce optimal level of green technological change. Acemoglu et al. (2012) demonstrates that subsidising clean technologies (and not dirty ones) is also necessary to break the lock-in of dirty technological change. Recommendations for technical changes are often based on climate considerations only and neglect secondary externalities and environmental costs of technology choices (such as loss of biodiversity due to inappropriate scale-up of bioenergy use). The scale of adverse side effects and co-benefits varies considerably between low-carbon technologies in the energy sector (Luderer et al. 2019).

16.2.4 Representation of the Innovation Process in Modelled Decarbonisation Pathways

A variety of models are used to generate climate mitigation pathways, compatible with 2°C and well below 2°C targets. These include integrated assessment models (IAMs), energy system models, computable general equilibrium models, and agent based models. They range from global (Chapter 3) to national models and include both top-down and bottom-up approaches (Chapter 4). Innovation in energy technologies, which comprises the development and diffusion of low-, zero- and negative-carbon energy options, but also investments to increase energy efficiency, is a key driver of emissions reductions in model-based scenarios.

16.2.4.1 Technology Cost Development

Assumptions on energy technology cost developments is one of the factors that determine the speed and magnitude of the deployment in climate-energy-economy models. The modelling is informed by the empirical literature that estimates the rates of cost reduction for energy technologies. A first strand of literature relies on the extrapolation of historical data, assuming that costs decrease either as a power law of cumulative production, exponentially with time (Nagy et al. 2013) or as a function of technical performance metrics (Koh and Magee 2008). Another approach relies on expert estimates of how future costs will evolve, including expert elicitations (Verdolini et al. 2018).

In these models, technology costs may evolve exogenously or endogenously (Mercure et al. 2016; Krey et al. 2019). In the first case, technology costs are assumed to vary over time at some predefined rate, generally extrapolated from past observed patterns or based on expert estimates. This formulation of cost dynamics generally underestimates future costs (Meng et al. 2021) as, among other things, it does not capture any policy-induced carbon-saving technological change or any spillover arising from the accumulation of national and international knowledge (Sections 16.2.2 and 16.2.3) or positive

macroeconomic effects of a transition (Karkatsoulis et al. 2016). The influence of cost and diffusion assumptions may be evaluated through sensitivity analysis. In the second case, costs are a function of a choice variable within the model. For instance, technology costs decrease as a function of either cumulative installed capacity (learning by doing) (Seebregts et al. 1998; Kypreos and Bahn 2003) or R&D investments or spillovers from other sectors and countries.

One factor in this ‘learning by researching’ is applied to a wide range of energy technologies but also to model improvements in the efficiency of energy use (Goulder and Schneider 1999; Popp 2004). More complex formulations include two-factor learning processes (Criqui et al. 2015; Emmerling et al. 2016; Paroussos et al. 2020) (Section 16.2.2.1), multifactor learning curves (Kahouli 2011; Yu et al. 2011), or other drivers of cost reduction such as economies of scale and markets (Elia et al. 2021). The application of two-factor learning curves to model energy technology costs is often constrained by the lack of information on public and/or private energy R&D investments in many fast-developing and developing countries (Verdolini et al. 2018). The approach used to model energy technology cost reductions varies across technologies, even within the same model, depending on the availability of data and/or the level of maturity. Less mature technologies generally depend highly on learning by research, whereas learning by doing dominates in more mature technologies (Jamassb 2007).

In addition to learning, knowledge spillover effects are also integrated in climate-energy-economy models to reflect the fact that innovation in a given country depends also on knowledge generated elsewhere (Emmerling et al. 2016; Fragkiadakis et al. 2020). Models with a more detailed representation of sectors (Paroussos et al. 2020) can use spillover matrices to include bilateral spillovers and compute learning rates that depend on the human capital stock and the regional and/or sectoral absorption rates (Fragkiadakis et al. 2020). Accounting for knowledge spillovers in the EU for PV, wind turbines, electric vehicles, biofuels, industry materials, batteries and advanced heating and cooking appliances can lead to the following results in a decarbonisation scenario over the period 2020–2050 as compared to the reference scenario: an increase of 1.0–1.4% in GDP, 2.1–2.3% in investment, and 0.2–0.4% in employment by clean energy technologies (Paroussos et al. 2017). When comparing two possible EU transition strategies – being a first-mover with strong unilateral emission reduction strategy until 2030 versus postponing action for the period after 2030 – endogenous technical progress in the green technologies sector can alleviate most of the negative effects of pioneering low-carbon transformation associated with loss of competitiveness and carbon leakage (Karkatsoulis et al. 2016).

16.2.4.2 Technology Deployment and Diffusion

To simulate possible paths of energy technology diffusion for different decarbonisation targets, models rely on assumptions about the cost of a given technology relative to the costs of other technologies, and its ability to supply the energy demand under the relevant energy system and physical constraints. These assumptions include, for example, considerations regarding renewable intermittency, inertia on technology lifetime (for instance, under less stringent temperature scenarios, early retirement of fossil plants does not take place), distribution, capacity

and market growth constraints, as well as the presence of policies. These factors change the relative price of technologies. Furthermore, technological diffusion in one country is also influenced by technology advancements in other regions (Kriegler et al. 2015).

Technology diffusion may also be strongly influenced, either positively or negatively, by a number of non-cost, non-technological barriers or enablers regarding behaviours, society and institutions (Knobloch and Mercure 2016). These include network or infrastructure externalities, the co-evolution of technology clusters over time ('path dependence'), the risk-aversion of users, personal preferences and perceptions and lack of adequate institutional framework which may negatively influence the speed of (low-carbon) technological innovation and diffusion, heterogeneous agents with different preferences or expectations, multi-objectives and/or competitiveness advantages and uncertainty around the presence and the level of environmental policies and institutional and administrative barriers (Marangoni and Tavoni 2014; Baker et al. 2015; Iyer et al. 2015; Napp et al. 2017; Biresselioglu et al. 2020; van Sluisveld et al. 2020). These types of barriers to technology diffusion are currently not explicitly detailed in most of the climate-energy-economy models. Rather, they are accounted for in models through scenario narratives, such as the ones in the *Shared Socioeconomic Pathways* (Riahi et al. 2017), in which assumptions about technology adoption are spanned over a plausible range of values. Complementary methods are increasingly used to explore their importance in future scenarios (Turnheim et al. 2015; Geels et al. 2016; Doukas et al. 2018; Gambhir et al. 2019; Trutnevyte et al. 2019). It takes a very complex modelling framework to include all aspects affecting technology cost reductions and technology diffusion, such as heterogeneous agents (Lamperti et al. 2020), regional labour costs (Skelton et al. 2020), materials cost and trade and perfect foresight multi-objective optimisation (Aleluia Reis et al. 2021). So far, no model can account for all these interactions simultaneously.

Another key aspect of decarbonisation regards issues of acceptability and social inclusion in decision-making. Participatory processes involving stakeholders can be implemented using several methods to incorporate qualitative elements in model-based scenarios on future change (van Vliet et al. 2010; Nikas et al. 2017, 2018; Doukas and Nikas 2020; van der Voorn et al. 2020).

16.2.4.3 Implications for the Modelling of Technical Change in Decarbonisation Pathways

Although the debate is still ongoing, preliminary conclusions indicate that integrated assessment models tend to underestimate innovation on energy supply but overestimate the contributions by energy efficiency (IPCC 2018b). Scenarios emerging from cost-optimal climate-energy-economy models are too pessimistic, especially in the case of rapidly changing technologies such as wind and batteries in the past decade. Conversely, they tend to be too optimistic regarding the timing of action, or the availability of a given technology and its speed of diffusion (Shiraki and Sugiyama 2020). Furthermore, some technological and economic transformations may emerge as technically feasible from IAMs, but are not realistic if taking into account political economy, international politics, human behaviours, and cultural factors (Bosetti 2021).

There is a range of projected energy technology supply costs included in the IPCC's Sixth Assessment Report (AR6) Scenario Database (Box 16.1). Variations of costs over time and across scenarios are within ranges comparable to those observed in recent years. Conversely, model results show that limiting warming to 2°C or 1.5°C will require faster diffusion of installed capacity of low-carbon energy options and a rapid phase-out of fossil-based options. This points to the importance of focusing on overcoming real-life barriers to technology deployment.

Box 16.1 | Comparing Observed Energy Technology Costs and Deployment Rates with Projections from AR6 Global Modelled Pathways

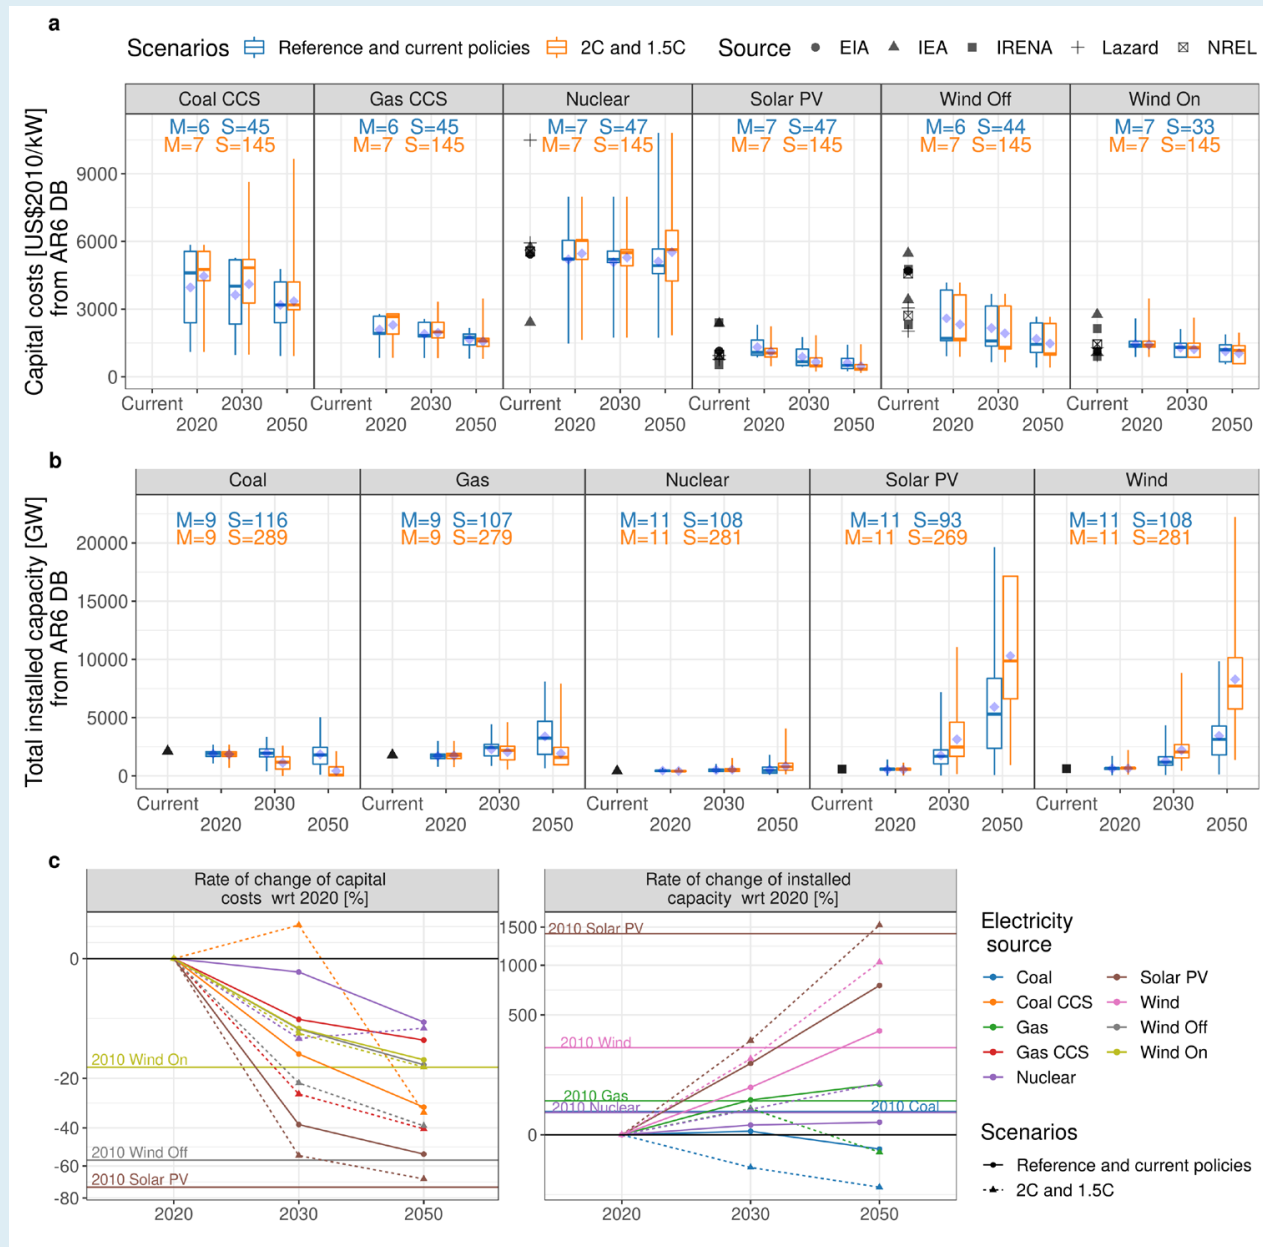

Currently observed costs and deployment for electricity supply technologies from a variety of sources are compared with projections from two different sets of scenarios contained in the AR6 Scenario database: (i) scenarios that limit warming to 3°C (>50%) and scenarios that limit warming to 4°C (>50%), and (ii) scenarios that limit warming to 2°C (>67%) or lower (AR6 Scenarios Database). Global aggregate costs are shown for the following technologies: coal with carbon dioxide capture and storage (CCS), gas with CCS, nuclear, solar PV, onshore and offshore wind.

The decrease in forecasted capital costs is not large compared to current capital costs for most technologies, and does not differ much between the two sets of scenarios (Box 16.1, Figure 1a). For offshore wind some of the models are more optimistic than the current reality (Timilsina 2020). Several sources of current solar PV costs report values that are at the low end of the AR6 Scenario Database. By 2050, the median technology cost forecasts decrease by between 5% for nuclear and 45–52% for solar (Box 16.1, Figure 1c).

Median values of renewables installed capacity increase with respect to 2020 capacity in scenarios that limit warming to 3°C (>50%) and in scenarios that limit warming to 4°C (>50%) (Box 16.1 Figure 1b), where energy and climate policies are implemented in line with NDCs announced prior to COP26. More stringent targets (2°C) are achieved through a higher deployment of renewable technologies: by 2050 solar (wind) capacity is estimated to increase by a factor of 15 (10) (Box 16.1, Figure 1c). This is accompanied by an almost complete phase-out of coal (–87%). The percentage of median changes in installed capacity in scenarios that limit warming to 3°C (>50%) and in scenarios that limit warming to 4°C (>50%) is within comparable ranges of that observed in the last decade. In the case of scenarios that limit warming to 2°C (>67%) or lower, capacity installed is higher for renewable technologies and nuclear, and lower for fossil-based technologies (Box 16.1, Figure 1c).

Box 16.1 (continued)

The higher deployment in scenarios that limit warming to 2°C (>67%) or lower cannot be explained solely as a result of technology cost dynamics. In IAMs, technology deployment is also governed by system constraints that characterise both 3°C (>50%) and 4°C (>50%) scenarios, for example, the flexibility of the energy system, the availability of storage technologies. From a modelling point of view, implementing more stringent climate policies to meet the 2°C limit forces models to find solutions, even if costly, to meet those intermittency and flexibility constraints and temperature target constraints.

Box 16.1, Figure 1 | Global technology cost and deployment in two groups of AR6 scenarios: (i) scenarios that limit warming to 3°C (>50%) and scenarios that limit warming to 4°C (>50%) ("Reference and current policies"), and (ii) scenarios that limit warming to 2°C (>67%) or lower ("2°C and 1.5°C"). Panel (a) Current capital costs are sourced from Table 1 (Timilsina 2020); distribution of capital costs in 2030 and 2050 (AR6 Scenarios Database). Blue symbols represent the mean. 'Current' capital costs for coal and gas plants with CCS are not available; Panel (b) Total installed capacity in 2019 (IEA 2020c; IRENA 2020a, b); distribution of total installed capacity in 2030 and 2050 (AR6 Scenario Database). Blue symbols represent the mean; Panel (c) Percentage of change in capital costs and installed capacity between (2010–2020) and percentage of median change (2020–2030 and 2020–2050) ($\text{Median}_{\text{year}} - \text{Median}_{2020} / \text{Median}_{2020} \times 100$). 'M' indicates the number of models, 'S' the number of scenarios for which this data is available. 'Reference and current policies' are scenarios that limit warming to 3°C (>50%) and scenarios that limit warming to 4°C (>50%) (C6 and C7 AR6 scenario categories). '2C and 1.5C' are scenarios that limit warming to 2°C (>67%) or lower (C1, C2 and C3 AR6 scenario categories). Each model may have submitted data for more than one model version.

16.3 A Systemic View of Technological Innovation Processes

The innovation process, which consists of a set of sequential phases (Section 16.2.1), is often simplified to a linear process. Yet, it is now well understood that it is also characterised by numerous kinds of interactions and feedbacks between the domains of knowledge generation, knowledge translation and application, and knowledge use (Kline and Rosenberg 1986). Furthermore, it is not just invention that leads to technological change; the cumulative contribution of incremental innovations over time can be very significant (Kline and Rosenberg 1986). Innovations can come, not just from formal research and development (R&D) but also sources such as production engineers and the shop floor (Kline and Rosenberg 1986; Freeman 1995).

This section reviews the literature focusing on innovation as a systemic process. This now predominant view enriches the understanding of innovation as presented in Section 16.2; it conceptualises innovation as the result of actions by, and interactions among, a large set of actors, whose activities are shaped by, and shape, the context in which they operate and the user group with which they are engaging. This section aligns with the discussion of socio-technical transitions (Section 1.7.3, Chapter 5 Supplementary Material, and Cross-Chapter Box 12 in this chapter).

16.3.1 Frameworks for Analysing Technological Innovation Processes

The resulting overarching framework that is commonly used in the innovation scholarship and in policy analyses is termed an ‘innovation system’, where the key constituents of the systems are actors, their interactions, and the institutional landscape, including formal rules, such as laws, and informal restraints, such as culture and codes of conduct, that govern the behaviour of the actors (North 1991).

One application of this framework, *national innovation systems (NIS)*, highlight the importance of national and regional relationships for determining the technological and industrial capabilities and development of a country (Lundvall 1992; Nelson 1993; Freeman 1995). Nelson (1993) and Freeman (1995) highlight the role of

institutions that determine the innovative performance of national firms as a way to understand differences across countries, while Lundvall (1992) focuses on the ‘elements and relationships which interact in the production, diffusion and use of new, and economically useful, knowledge’ – that is, notions of interactive learning, in which user-producer relationships are particularly important (Lundvall 1988). Building on this, various other applications of the ‘innovation system’ framework have emerged in the literature.

Technological innovation systems (TIS), with a technology or a set of technologies (more narrowly or broadly defined in different cases) as the unit of analysis, focus on explaining what accelerates or hinders their development and diffusion. Carlsson and Stankiewicz (1991) define a technological system as ‘a dynamic network of agents interacting in a specific economic/industrial area under a particular institutional infrastructure and involved in the generation, diffusion, and utilisation of technology’. More recent work takes a ‘functional approach’ to TIS (Hekkert et al. 2007; Bergek et al. 2008), which was later expanded with explanations of how some of the sectoral, geographical and political dimensions intersect with technology innovation systems (Bergek et al. 2015; Quitzow 2015).

Sectoral innovation systems (SIS) are based on the understanding that the constellation of relevant actors and institutions will vary across industrial sectors, with each sector operating under a different technological regime and under different competitive or market conditions. A sectoral innovation, thus, can be defined as ‘that system (group) of firms active in developing and making a sector’s products and in generating and utilising a sector’s technologies’ (Breschi and Malerba 1997).

Regional innovation systems (RIS) and global innovation systems (GIS), recognise that the many innovation processes have a spatial dimension, where the development of system resources such as knowledge, market access, financial investment, and technology legitimacy may well draw on actors, networks, and institutions within a region (Cooke et al. 1997). In other cases, the distribution of many innovation processes are highly internationalised and therefore outside specific territorial boundaries (Binz and Truffer 2017). Importantly, Binz and Truffer (2017) note that the GIS framework ‘differentiates between an industry’s dominant innovation mode...

Table 16.5 | Functions that the literature identified as key for well-performing technological innovation systems. Source: based on Hekkert et al. (2007) and Bergek et al. (2008).

Functions	Description
Entrepreneurial activities and experimentation	Entrepreneurial activities and experimentation for translating new knowledge and/or market opportunities into real-world application
Knowledge development	Knowledge development includes both learning by searching and learning by doing
Knowledge diffusion	Knowledge diffusion through networks, both among members of a community (e.g., scientific researchers) and across communities (e.g., universities, business, policy, and users)
Guidance of search	Guidance of search directs the investments in innovation in consonance with signals from the market, firms or government
Market formation	Market formation through customers or government policy is necessary to allow new technologies to compete with incumbent technologies
Resource mobilisation	Resource mobilisation pertains to the basic inputs – human and financial capital – to the innovation process
Creation of legitimacy/counteract resistance to change	Creation of legitimacy or counteracting resistance to change, through activities that allow a new technology to become accepted by users, often despite opposition by incumbent interests
Development of external economies	Development of external economies, or the degree to which other interests benefit from the new technology

and the economic system of valuation in which markets for the innovation are constructed’.

The relevance of *mission-oriented innovation systems (MIS)*, comes into focus with the move towards mission-oriented programmes as part of the increasing innovation policy efforts to address societal challenges. Accordingly, an MIS is seen as consisting of ‘networks of agents and sets of institutions that contribute to the development and diffusion of innovative solutions with the aim to define, pursue and complete a societal mission’ (Hekkert et al. 2020).

Notably the innovation systems approach has been used in a number of climate-relevant areas such as agriculture (Echeverría 1998; Horton and Mackay 2003; Brooks and Loevinsohn 2011; Klerx et al. 2012), energy (Sagar and Holdren 2002; OECD 2006; Gallagher et al. 2012; Wiczorek et al. 2013; Darmani et al. 2014; Mignon and Bergek 2016), industry (Koasidis et al. 2020b) and transport (Koasidis et al. 2020a), and sustainable development (Anadon et al. 2016b; Clark et al. 2016; Bryden and Gezelius 2017; Nikas et al. 2020).

A number of functions can be used to understand and characterise the performance of technological innovation systems (Hekkert et al. 2007; Bergek et al. 2008). The most common functions are listed in Table 16.5.

Evidence from empirical case studies indicates that all the above functions are important and that they interact with one another (Hekkert and Negro 2009). The approach therefore serves as both a rationale for and a guide to innovation policy (Bergek et al. 2010).

A much-used, complementary systemic framework is the Multi-Level Perspective (MLP) (Geels 2002), which focuses mainly on the diffusion of technologies in relation to incumbent technologies in their sector and the overall economy. A key point of MLP is that new technologies need to establish themselves in a stable ‘socio-technical regime’ and are therefore generally at a disadvantage, not just because of their low technological maturity, but also because of an unwelcoming system. The MLP highlights that the uptake of technologies in society is an evolutionary process, which can be best understood as a combination of ‘variation, selection and retention’ as well as ‘unfolding and reconfiguration’ (Geels 2002). Thus, new technologies in their early stages need to be selected and supported at the micro-level by niche markets, possibly through a directed process that has been termed ‘strategic niche management’ (Kemp et al. 1998). As, at the landscape level, pressures on incumbent regimes mount, and those regimes destabilise, the niche technologies get a chance to get established in a new socio-technical regime. This allows these technologies to grow and stabilise, shaping a changed or sometimes radically renewed socio-technical regime. The MLP takes a systematic and comprehensive view about how to nurture and shape technological transitions by understanding them as evolutionary, multidirectional and cumulative socio-technical processes playing out at multiple levels over time, with a concomitant expansion in the scale and scope of the transition (Elzen et al. 2004; Geels 2005). There have been numerous studies that draw on the MLP to understand different aspects of climate technology innovation and diffusion (van Bree et al. 2010; Geels 2012; Geels et al. 2017).

Systemic analyses of innovation have predominantly focused on industrialised countries. There have been some efforts to use the innovation systems lens for the developing country context (Jacobsson and Bergek 2006; Altenburg 2009; Lundvall et al. 2009; Tigabu et al. 2015; Tigabu 2018; Choi and Zo 2019) and specific suggestions on ways for developing countries to strengthening their innovation systems (e.g., by universities taking on a ‘developmental’ role (Arocena et al. 2015), or industry associations acting as intermediaries to build institutional capacities (Watkins et al. 2015; Khan et al. 2020), including specifically for addressing climate challenges (Sagar et al. 2009; Ockwell and Byrne 2016). But the conditions in developing countries are quite different, leading to suggestions that different theoretical conceptualisations of the innovation systems approach may be needed for these countries (Arocena and Sutz 2020), although a system perspective would still be appropriate (Boodoo et al. 2018).

16.3.2 Identifying Systemic Failures to Innovation in Climate-related Technologies

Traditional perspectives on innovation policy were mostly science-driven, and focused on strengthening invention and its translation into application in a narrow sense. Also, a second main traditional perspective on innovation policy was focused on correcting for ‘market failures’ (Weber and Truffer 2017) (Section 16.2). The more recent understanding of, and shift of focus to, the systemic nature on the innovation and diffusion of technologies has implications for innovation policy, since innovation outcomes depend not just on inputs such as R&D, but much more on the functioning of the overall innovation system (see Sections 16.3.1 and 16.4). Policies can therefore be directed at innovation systems components and processes that need the greatest attention or support. This may include, for example, strengthening the capabilities of weak actors and improving interactions between actors (Jacobsson et al. 2017; Weber and Truffer 2017). At the same time, a systemic perspective also brings into sharp relief the notion of ‘system failures’ (Weber and Truffer 2017).

Systemic failures include: infrastructural failures; hard (e.g., laws, regulation) and soft (e.g., culture, social norms) institutional failures; interaction failures (strong and weak network failures); capability failures relating to firms and other actors; lock-in; and directional, reflexivity, and coordination failures (Klein Woolthuis et al. 2005; Chaminade and Esquist 2010; Negro et al. 2012; Weber and Rohracher 2012; Wiczorek and Hekkert 2012). Most of the literature that unpacks such failures and explores ways to overcome them is on energy-related innovation policy. For example, Table 16.6 summarises a meta-study (Negro et al. 2012) that examined cases of renewable energy technologies trying to disrupt incumbents across a range of countries to understand the roles, and relative importance, of the ‘systemic problems’ highlighted in Section 16.3.1.

Depending on the sector, specific technology characteristics, and national and regional context, the relevance of these systemic problems varies (Trianni et al. 2013; Bauer et al. 2017; Wesseling and Van der Vooren 2017; Koasidis et al. 2020a, b), suggesting that the innovation policy mix has to be tailor-made to respond to the diversity

of systemic failures (Rogge et al. 2017). An illustration of how such systemic failures have been addressed is given in Box 16.2, which shows how the Indian government designed its standards and labelling programme for energy-efficient air conditioners and refrigerators.

The success of this programme resulted from the careful attention to bring on board and coordinate the relevant actors and resources, the design of the standards, and ensuring effective administration and enforcement of the standards (Malhotra et al. 2021).

Table 16.6 | Examination of systemic problems preventing renewable energy technologies from reaching their potential, including number of case studies in which the particular 'systemic problem' was identified. Source: Negro et al. (2012).

Systemic problems	Empirical sub-categories	No. of cases
Hard institutions	<ul style="list-style-type: none"> – 'Stop and go policy': lack of continuity and long-term regulations; inconsistent policy and existing laws and regulations – 'Attention shift': policymakers only support technologies if they contribute to the solving of a current problem – 'Misalignment' between policies on sector level such as agriculture, waste, and on governmental levels, i.e., EU, national, regional level, etc. – 'Valley of Death': lack of subsidies, feed-in tariffs, tax exemption, laws, emission regulations, venture capital to move technology from experimental phase towards commercialisation phase 	51
Market structures	<ul style="list-style-type: none"> – Large-scale criteria – Incremental/near-to-market innovation – Incumbent's dominance 	30
Soft institutions	<ul style="list-style-type: none"> – Lack of legitimacy – Different actors opposing change 	28
Capabilities/capacities	<ul style="list-style-type: none"> – Lack of technological knowledge of policymakers and engineers – Lack of ability of entrepreneurs to pack together, to formulate clear message, to lobby to the government – Lack of users to formulate demand – Lack of skilled staff 	19
Knowledge infrastructure	<ul style="list-style-type: none"> – Wrong focus or not specific courses at universities knowledge institutes – Gap/misalignment between knowledge produced at universities and what is needed in practice 	16
Too weak interactions	<ul style="list-style-type: none"> – Individualistic entrepreneurs – No networks, no platforms – Lack of knowledge diffusion between actors – Lack of attention for learning by doing 	13
Too strong interactions	<ul style="list-style-type: none"> – Strong dependence on government action or dominant partners (incumbents) – Networks allows no access to new entrants 	8
Physical infrastructure	<ul style="list-style-type: none"> – No access to existing electricity or gas grid for renewable energy technologies – No decentralised, small-scale grid – No refill infrastructure for biofuels, hydrogen, biogas 	2

Box 16.2 | Standards and Labelling for Energy Efficient Refrigerators and Air Conditioners in India²

Energy efficiency is often characterised as a 'low-hanging fruit' for reducing energy use. However, systemic failures such as lack of access to capital, hidden costs of implementation, and imperfect information can result in low investments into adoption and innovation in energy efficiency measures (Sorrell et al. 2004). To address such barriers, India's governmental Bureau of Energy Efficiency (BEE) introduced the Standards and Labelling (S&L) programme to promote innovation in energy efficient appliances in 2006 (Sundaramoorthy and Walia 2017). While context-dependent, the programme's design, policies and scale-up contain lessons for addressing systemic failures elsewhere too.

Programme design and addressing of early systemic barriers

To design the S&L programme, BEE drew on the international experiences and technical expertise of the Collaborative Labelling and Appliance Standards Program (CLASP) – a non-profit organisation that provides technical and policy support to governments in implementing S&L programmes. For example, since there was no data on the efficiency of appliances in the Indian market, CLASP assisted with early data collection efforts, resulting in a focus on refrigerators and air conditioners (McNeil et al. 2008).

² This section draws on *The role of capacity-building in policies for climate change mitigation and sustainable development: The case of energy efficiency in India*, (Malhotra et al. 2021).

Box 16.2 (continued)

Besides drawing from international knowledge, the involvement of manufacturers, testing laboratories, and customers was crucial for the functioning of the innovation system.

To involve manufacturers, BEE employed three strategies to set the standards at an ambitious yet acceptable level. First, BEE enlisted the Indian Institute of Technology (IIT) Delhi (a public technical university) to engage with manufacturers and to demonstrate cost-effective designs of energy-efficient appliances. Second, BEE agreed to make the standards voluntary from 2006 to 2010. In return, the manufacturers agreed to mandatory and progressively more stringent standards starting in 2010. Third, BEE established a multistakeholder committee with representation from BEE, the Bureau of Indian Standards, appliance manufacturers, test laboratories, independent experts, and consumer groups (Jairaj et al. 2016) to ensure that adequately stringent standards are negotiated every two years.

At this time, India had virtually no capacity for independent testing of appliances. Here, too, BEE used multiple approaches towards creating the actors and resources needed for the innovation system to function. First, BEE funded the Central Power Research Institute (CPRI) – a national laboratory for applied research, testing and certification of electrical equipment – to set up refrigerator and AC testing facilities. Second, they invited bids from private laboratories, thus creating a demand for testing facilities. Third, BEE developed testing protocols in partnership with universities. Australian standards for testing frost-free refrigerators were adopted until local standards were developed. Thus, once the testing laboratories, protocols and benchmark prices for testing were in place, the appliance manufacturers could employ their services.

Finally, a customer outreach programme was conducted from 2006 to 2008 to inform customers about energy-efficient appliances, to enable them to interpret the labels correctly, and to understand their purchase decisions and information sources (Jain et al. 2018; Joshi et al. 2019). BEE initiated a capacity-building programme for retailers to be an information source for customers. A comprehensive document with details of different models and labels was provided to retailers, together with a condensed booklet to be shared with customers.

Adapting policies to technologies and local context

While many of India's standards and testing protocols were based on international standards, they needed to be adapted to the Indian context. For example, because of higher temperatures in India, the reference outside temperature of 32°C for refrigerators was changed to 36°C.

AC testing protocols also had to be adapted because of the emergence of inverter-based ACs. Existing testing done only at a single temperature did not value inverter-based ACs' better average performance as compared to fixed-speed ACs over a range of temperatures. Thus, the Indian Seasonal Energy Efficiency Ratio (ISEER) was developed for Indian temperature conditions in 2015 by studying International Organization for Standardization (ISO) standards and through consultations with manufacturers (Mukherjee et al. 2020).

These measures had multiple effects on technological change. As a result of stringent standards, India has some of the most efficient refrigerators globally. In the case of ACs, the ISEER accelerated technological change by favouring inverter-based ACs over fixed-speed ACs, driving down their costs and increasing their market shares (BEE 2020).

Scaling up policies for market transformation

As the S&L programme was expanded, BEE took measures to standardise, codify and automate it. For example, to process a high volume of applications for labels efficiently, an online application portal with objective and transparent certification criteria was created. This gave certainty to the manufacturers, enabling diversity and faster diffusion of energy-efficient appliances. Thus by 2019, the programme expanded to cover thousands of products across 23 appliance types (BEE 2020).

Besides issuing labels, the enforcement of standards also needed to be scaled up efficiently. BEE developed protocols for randomly sampling appliances for testing. Manufacturers were given a fixed period to rectify products that did not meet the standards, failing which they would be penalised and the test results would be made public.

16.3.3 Indicators for Technological Innovation

Assessing the state of technological innovation helps in understanding the progress of current efforts and policies in meeting stated objectives, and how we might design policies to do better.

Traditionally, input measures such as research, development and demonstration (RD&D) investments, and output measures such as scientific publication and patents were used to characterise innovation activities (Freeman and Soete 2009). This is partly because of the successes of specialised R&D efforts (Freeman 1995), the predominant linear model of innovation, and because such measures

can (relatively) easily be obtained and compared. In the realm of energy-related innovation, RD&D investments remain the single most-used indicator to measure inputs into the innovation process (Box 16.3). Patent counts are a widely used indicator of the outputs of the innovation process, especially because they are detailed enough to provide information on specific adaptation and mitigation technologies. Mitigation and adaptation technologies have their own classification (Y02) with the European Patent Office (EPO) (Veefkind et al. 2012; Angelucci et al. 2018), which can be complemented with keyword search and manual inspection (Persoon et al. 2020; Surana et al. 2020b). However, using energy-related patents as an indicator of innovative activities is complicated by several issues (de Rassenfosse

Box 16.3 | Investments in Public Energy Research and Development

Public energy R&D investments are a crucial driver of energy technology innovation (Sections 16.2.1.1 and 16.4.1). Box 16.3, Figure 1 shows the time profile of energy-related RD&D budgets in OECD countries as well as some key events which coincided with developments of spending (IEA 2019). Such data on other countries, in particular developing countries, are not available, although recent evidence suggests that expenditures are increasing there (IEA 2020c). The IEA collected partial data from China and India in the context of Mission Innovation, but this is only available starting from 2014 and thus not included in Figure 1.

The figure illustrates two points. First, energy-related RD&D has risen slowly in the last 20 years, and is now reaching levels comparable with the peak of energy RD&D investments following the two oil crises. Second, over time there has been a reorientation of the portfolio of funded energy technologies away from nuclear energy. In 2019, around 80% of all public energy RD&D spending was on low-emission technologies – energy efficiency, carbon dioxide capture, use and storage, renewables, nuclear, hydrogen, energy storage and cross-cutting issues such as smart grids. A more detailed discussion of the time profile of RD&D spending in IEA countries, including as a share of GDP, is available in IEA (2020b).

Box 16.3, Figure 1 | Fraction of public energy RD&D spending by technology over time for IEA (largely OECD) countries between 1974 and 2018.
Sources: RD&D Database (2019), IEA (2019) (extracted on November 11, 2020).

et al. 2013; Haščič and Migotto 2015; Jaffe and de Rassenfosse 2017), including the fact that the scope of what are considered climate mitigation inventions is not always clear or straightforward.

Conversely, private energy R&D investments and investments by financing firms cannot be precisely assessed for a number of reasons, including limited reporting and the difficulty of singling out energy-related investments. This inability to precisely quantify private investments in energy R&D leads to a patchy understanding of the energy innovation system, and how private energy R&D investments responds to public energy R&D investments. Overall, evidence shows that some of the industrial sectors that are important for meeting climate goals (electricity, agriculture and forestry, mining, oil and gas, and other energy-intensive industrial sectors) are investing relatively small fractions of sales on R&D (*medium evidence, high agreement*) (Jasmab and Pollitt 2005; Jamasb and Pollitt 2008; Sanyal and Cohen 2009; European Commission 2015; American Energy Innovation Council 2017; Gaddy et al. 2017; National Science Board 2018).

Financing firms also play an important role in the energy innovation process, but data availability is limited. The venture capital (VC) financing model, used to overcome the 'valley of death' in the biotech and IT space (Frank et al. 1996), has not been as suitable for hardware start-ups in the energy space: for example, the percentage of exit outcomes in cleantech start-ups was almost half of that in medical start-ups, and less than a third of software investments (Gaddy et al. 2017). The current VC model and other private finance do not sufficiently cover the need to demonstrate energy technologies at scale (Anadón 2012; Mazzucato 2013; Nemet et al. 2018). This greater difficulty in reaching the market compared to other sectors

may have contributed to a reduction in private equity and venture capital finance for renewable energy technologies after the boom of the late 2000s (Frankfurt School-UNEP Centre/BNEF 2019).

Quantitative indicators such as energy-related RD&D spending are insufficient for the assessment of innovation systems (David and Foray 1995): they only provide a partial view into innovation activities, and one that is potentially misleading (Freeman and Soete 2009). Qualitative indicators measuring the more intangible aspects of the innovation process and system are crucial to fully understand the innovation dynamics in a climate or energy technologies or sectors (Gallagher et al. 2006), including in relation to adopting an adaptive learning strategy and supporting learning through demonstration projects (Chan et al. 2017).

In Table 16.7, both quantitative and qualitative indicators for systemic innovation are outlined, using clean energy innovation as an illustrative example, and drawing on a broad literature base, taking into account both the input-output-outcome classification and its variations (Freeman and Soete 1997; Sagar and Holdren 2002; Hu et al. 2018), combined with the functions of technological innovation systems (Miremadi et al. 2018), while also being cognisant of the specific role of key actors and institutions (Gallagher et al. 2012). A specific assessment of innovation may focus on part of such a list of indicators, depending on what aspect of innovation is being studied, whether the analysis takes a more or less systemic perspective, and the specific technology and geography considered. Similarly, innovation policies may be designed to specifically boost only some of these aspects, depending on whether a given country/region is committed to strengthen a given technology or phase.

Table 16.7 | Commonly used quantitative innovation metrics, organised by inputs, outputs and outcomes. Sources: based on Sagar and Holdren (2002); Gallagher et al. (2006, 2011, 2012); Hekkert et al. (2007); Gruebler et al. (2012); Hu et al. (2018); Miremadi et al. (2018); Avelino et al. (2019).

Function	Input indicators	Output indicators	Outcome indicators	Actors	Policies	Structural and systemic indicators
Knowledge development	Higher education investments Research and development (R&D) investments Number of researchers R&D projects over time	Scientific publications Highly-cited publications Patents New product configurations	Number of technologies developed (proof-of-concept/prototypes) Increase in number of researchers Learning rates	Governments Private corporations Universities	Research programmes and strategies Intellectual Property Rights (IPR) policies International technical norms (e.g., standards) Higher education policies	Well-defined processes to define research priorities Stakeholder involvement in priority-setting
Knowledge diffusion	R&D networks Number of research agreements Number of research exchange programmes Number of scientific conferences	Citations to literature or patents Public-private co-publications Co-patenting Number of co-developed products International scientific co-publications Number of workshops and conferences	Number of licensed patents Number of technologies transferred Knowledge-intensive services exports Number of patent applications by foreigners Number of researchers working internationally	Governments Private corporations Scientific societies Universities	Development of communication centres Facilitation of the development of networks Open-access publication policies IPR policies International policy: e.g., treaties, clean development mechanism	Accessibility to exchange programmes Strength of linkage among key stakeholders Participation to framework agreements ICT access

Function	Input indicators	Output indicators	Outcome indicators	Actors	Policies	Structural and systemic indicators
Guidance of search	Policy action plans and long-term targets Shared strategies and roadmaps Articulation of interest from lead customers Expectations of markets/profits	Level of media coverage Scenarios and foresight projects	Budget allocations Mission-oriented innovation programmes	Governments Interest groups Media	Targets set by government for industry Innovation policies Credible political support	Media strength
Resource mobilisation	Access to finance Graduate in Science, Technology, Engineering, and Mathematics (STEM) Gross expenditure on R&D/total expenditure Domestic credit to private sector Number of researchers in R&D per capita Public energy R&D expenditure/total expenditure Expenditure on education Investment in complementary assets and/or infrastructure (e.g., charging infrastructure for electric vehicles, smart grids) Venture capital on deals	Number of green projects/technologies funded Share of domestic credit granted to low-carbon technology projects Share of domestic credit granted to projects developing complementary assets/infrastructure	Employment in knowledge-intensive activities Employment in relevant industries Scale of innovative activities Rate of growth of dedicated investment Availability of complementary assets and infrastructure	Governments Private firms Private investors (angel, venture capital, private equity) Banks	Financial resources support Development of innovative financing International agreements (e.g., technology agreements) Infrastructure support Project/programme evaluation Innovation policies Higher education policies	
Entrepreneurial activities	Number of new entrants Percentage of clean energy start-ups/incumbents Access to finance for cleantech start-ups	Small and medium-sized enterprises (SMEs) introducing product or process innovation Market introduction of new technological products Number of new businesses Experimental application projects Creative goods exports		Private firms Government Risk-capital providers Philanthropists	Ease of starting a business Risk-capital policies Start-up support programmes Incubator programmes	Start-up support services
Market formation	Public market support High-tech imports	Market penetration of new technologies Increase in installed capacity Number of niche markets Number of technologies commercialised	Environmental performance Level of environmental impact on society Renewable energy jobs Renewable energy production Trade of energy technology and equipment High-tech exports	Private firms Governments institutions regulating trade, finance, investment, environment, development, security, and health issues	Environmental and energy regulation Fiscal and financial incentives Cleantech-friendly policy processes Transparency Specific tax regimes	Resource endowments Attractiveness of renewable energy infrastructure Coordination across relevant actors (e.g., renewable energy producers, grid operators, and distribution companies)
Creation of legitimacy	Youth and public demonstration Lobbying activities Regulatory acceptance and integration Technology support	Level of discussion/debate among key stakeholders (public, firms, policymakers, etc.) Greater recognition of benefits	Public opinion Policymaker opinion Executive opinion on regulation Environmental standards and certification	Governments Stakeholders Citizens Philanthropists	Regulatory quality Regulatory instruments Political consistency	Participatory processes

The systemic approach to innovation and transition dynamics (Cross-Chapter Box 12 in this chapter) has advanced our understanding of the complexity of the innovation process, pointing to the importance of assessing the efficiency and effectiveness in producing, diffusing and exploiting knowledge (Lundvall 1992), including how the existing stock of knowledge may be recombined and used for new applications (David and Foray 1995). There remains a crucial need for more relevant and comprehensive approaches of assessing innovation (Freeman and Soete 2009; Dziallas and Blind 2019). In the context of climate mitigation, innovation is a means to an end; therefore, there is the need to consider the processes by which the output of innovation (e.g., patents) are translated into real-world outcomes (e.g., deployment of low-carbon technologies) (Freeman and Soete 1997; Sagar and Holdren 2002). Currently, there is no available set of quantitative metrics that, collectively, can help get a picture of innovation in a particular energy technology or set of energy technologies. Also we are still lacking an understanding of how to systematically use qualitative indicators to characterise the more intangible aspects of the energy innovation system and to improve front-end innovation decisions (Dziallas and Blind 2019).

16.3.4 Emerging Policy Perspectives on Systemic Transformations

Because of the multiple market, government, system, and other failures that are associated with the energy system, a range of policy interventions are usually required to enable the development and introduction of new technologies in the market (Jaffe et al. 2005; Burer and Wüstenhagen 2009; Negro et al. 2012; Twomey 2012; Veugelers 2012; Weber and Rohrer 2012) used in what is termed as 'policy mixes' (Rogge and Reichardt 2016; Edmondson et al. 2019, 2020; Rogge et al. 2020). Empirical research shows that, in the energy and environment space, when new technologies were developed and introduced in the market, it was usually at least partly as a result of a range of policies that shaped the socio-technical system (*robust evidence, high agreement*) (Bunn et al. 2014; Bergek et al. 2015; Rogge and Reichardt 2016; Nemet 2019). An example of this systemic and dynamic nature of policies is the 70-year innovation journey of solar photovoltaic (PV), covering multiple countries, which is reviewed in Box 16.4.

Box 16.4 | Sources of Cost Reductions in Solar Photovoltaics

No single country persisted in developing solar photovoltaic (PV): five countries each made a distinct contribution, with each leader relinquishing its lead. The free flow of ideas, people, machines, finance, and products across countries explains the success of solar PVs. Barriers to knowledge flow delay innovation.

Solar PV has attracted interest for decades, and until recently was seen as an intriguing novelty, serving a niche, but widely dismissed as a serious answer to climate change and other social problems associated with energy use. Since the IPCC's Fifth Assessment Report (AR5), PV has become a substantial global industry – a truly disruptive technology that has generated trade disputes among superpowers, threatened the solvency of large energy companies, and prompted reconsideration of electric utility regulation rooted in the 1930s. More favourably, its continually falling costs and rapid adoption are improving air quality and facilitating climate change mitigation. PV is now so inexpensive that it is important in an expanding set of countries. In 2020, 41 countries, in six continents, had each installed at least 1GW of solar (IRENA 2020a).

The cost of generating electricity from solar PV is now lower in sunny locations than running existing fossil fuel power plants (IEA 2020c) (Chapter 6). Prices in 2020 were below where even the most optimistic experts expected they would be in 2030.

The costs of solar PV modules have fallen by more than a factor of 10,000 since they were first commercialised in 1957. This four orders of magnitude cost reduction from the first commercial application in 1958 until 2018 can be summarised as the result of distinct contributions by the USA, Japan, Germany, Australia, and China – in that sequence (Green 2019; Nemet 2019). As shown in Box 16.4, Figure 1, PV improved as the result of:

- i. scientific contributions in the 1800s and early 1900s, in Europe and the USA, that provided a fundamental understanding of the ways that light interacts with molecular structures, leading to the development of the p-n junction to separate electrons and holes (Einstein 1905; Ohl 1941);
- ii. a breakthrough at a corporate laboratory in the USA in 1954 that made a commercially available PV device available and led to the first substantial orders, by the US Navy in 1957 (Ohl 1946; Gertner 2013);
- iii. a government R&D and public procurement effort in the 1970s in the USA, that enlisted skilled scientists and engineers into the effort and stimulated the first commercial production lines (Christensen 1985; Blieden 1999; Laird 2001);
- iv. Japanese electronic conglomerates, with experience in semiconductors, serving niche markets in the 1980s and in 1994 launching the world's first major rooftop subsidy programme, with a declining rebate schedule, and demonstrating there was substantial consumer demand for PV (Kimura and Suzuki 2006);
- v. Germany passing a feed-in tariff in 2000 that quadrupled the market for PV, catalysing development of PV-specific production equipment that automated and scaled PV manufacturing (RESA 2001; Lauber and Jacobsson 2016);

Box 16.4 (continued)

Box 16.4, Figure 1 | Milestones in the development of low-cost solar photovoltaics. Source: Nemet (2019).

- vi. Chinese entrepreneurs, almost all trained in Australia and using Australian-invented passivated emitter rear cell technology, building supply chains and factories of gigawatt scale in the 2000s. China became the world's leading installer of PVs from 2013 onward (Quitow 2015; Helveston and Nahm 2019); and
- vii. a cohort of adopters with high willingness to pay, accessing information from neighbours, and installer firms that learnt from their installation experience as well as that of their competitors, to lower soft costs (Ardani and Margolis 2015; Gillingham et al. 2016).

As this evolution makes clear, no individual country persisted in leading the technology, and every world-leading firm lost its lead within a few years (Green 2019). Solar followed an overlapping but sequential process of technology creation, market creation and cost reduction (comparable to emergence, early adoption, diffusion and stabilisation in Cross-Chapter Box 12 in this chapter). In the technology creation phase, examples of central processes include flows of knowledge from one person to another, between firms, and between countries as well as US and Japanese R&D funding in the 1970s and early 1980s. During market creation, PVs modular scale allowed it to serve a variety of niche markets from satellites in the 1950s to toys in the 1980s, when Germany transformed the industry from niche to mass market with its subsidy programme that began in 2000 and became important for PV in 2004. The dramatic increase in size combined with its 20-year guaranteed contracts reduced risk for investors and created confidence in PV's long-term growth. Supportive policies also emerged outside Germany, in Spain, Italy, California, and China, which spread the risk, even as national policy support was more volatile. Rapid and deep cost reductions were made possible by: learning by doing in the process of operating, optimising, and combining production equipment; investing and improving each manufacturing line to gradually scale up to massive sizes; and incremental improvements in the PV devices themselves.

Central to PV development has been its modularity, which provided two distinct advantages: access to niche markets, and iterative improvement. Solar has been deployed as a commercial technology across nine orders of magnitude: from a 1W cell in a calculator to a 1GW plant in the Egyptian desert, and almost every scale in between. This modular scale enabled PV to serve a sequence of policy-independent niche markets (such as satellites and telecoms applications), which generally increased in size and decreased in willingness to pay, in line with the technology cost reductions. This modular scale also enabled a large number of iterations, such that in 2020 over three billion solar panels had been produced. Compared to, for instance, approximately 1000 nuclear reactors that were ever constructed, a million times more opportunities for learning by doing were available to solar PV: to make incremental improvements, to introduce new manufacturing equipment, to optimise that equipment, and to learn from failures. More generally, recent work has pointed to the benefits of modularity in the speed of adoption (Wilson et al. 2020) and learning rates (Sweerts et al. 2020).

While many technologies do not fit into the solar model, some – including micro nuclear reactors and direct air capture – also have modular characteristics that make them suitable for following solar's path and benefit from solar's drivers. However, it took solar PV 60 years to become cheap, which is too slow for addressing climate change if a technology is now still at the lab scale. A challenge in learning from the solar model is therefore how to use public policy to speed up innovation over much shorter time frames, for example, 15 or fewer years.

There are many definitions of policy mixes from various disciplines (Rogge et al. 2017), including environmental economics (Lehmann 2012), policy studies (Kern and Howlett 2009) and innovation studies. Generally speaking, a policy mix can be characterised by a combination of building blocks, namely elements, processes and characteristics, which can be specified using different dimensions (Rogge and Reichardt 2016). Elements include: (i) the policy strategy with its objectives and principal plans; (ii) the mix of policy instruments; and (iii) instrument design. The content of these elements is the result of policy processes. Both elements and processes can be described by their characteristics in terms of the consistency of the elements, the coherence of the processes, and the credibility and comprehensiveness of the policy mix in different policy, governance, geography and temporal context (Rogge and Reichardt 2016). Other aspects in the evaluation of policy mixes include framework conditions, the type of policy instrument and the lower level of policy granularity, namely design elements or design features (del Río 2014; del Río and Cerdá 2017). In addition, many have argued for the need to craft policies that affect different actors in the transition, some supporting and some 'destabilising' (Geels 2002; Kivimaa and Kern 2016).

Learning from the innovation systems literature, some of the recent policy focus is not only directed on innovation policies that can optimise the innovation system to improve economic competitiveness and growth, but also policies that can induce strategic directionality and guide processes of transformative changes towards desired societal objectives (Mitcham 2003; Steneck 2006). Therefore, the aim is to connect innovation policy with societal challenges and transformative changes through engagement with a variety of actors and ideas and incorporating equity, nowadays often referred to as a 'just transition' (Newell and Mulvaney 2013; Swilling et al. 2016; Heffron and McCauley 2018; Jasanoff 2018) (Chapters 1 and 17). This new policy paradigm is opening up a new discursive space, shaping policy outcomes, and giving rise to the emerging idea of transformative innovation policy (Fagerberg 2018; Diercks et al. 2019).

Transformative innovation policy has a broader coverage of the innovation process with a much wider participation of actors, activities and modes of innovation. It is often expressed as socio-technical transitions (Elzen et al. 2004; Turnheim and Sovacool 2020) or societal transformations (Scoones 2015; Roberts et al. 2018). Transformative innovation policy encompasses different ideas and concepts that aim to address the societal challenges involving a variety of discussions, including social innovation (Mulgan 2012), complex adaptive systems (Gunderson and Holling 2002), eco-innovation (Kemp 2011) and a framework for responsible innovation (Stilgoe et al. 2013), value-sensitive design (Friedman and Hendry 2019) and social-technical integration (Fisher et al. 2006).

16.4 Innovation Policies and Institutions

Building on the frameworks for identifying market failures (Section 16.2) and systemic failures (Section 16.3) in the innovation system for climate-related technologies, Section 16.4 proceeds as follows. First, it considers some of the policy instruments introduced in Chapter 13 that are particularly relevant for the pace and direction of innovation in technologies for climate change mitigation and adaptation. Second, it explains why governments put in place policies to promote innovation in climate-related technologies. Third, it takes stock of the overall empirical and theoretical evidence regarding the relationship between policy instruments with a direct and an indirect impact on innovation outcomes (including intellectual property regimes) and also other outcomes (competitiveness and distributional outcomes). Fourth, it assesses the evidence on the impact of trade-related policies and of sub-national policies aiming to develop cleantech industrial clusters.

This section focuses on innovation policies and institutions which are implemented at the national level. Whenever relevant, this section highlights examples of policies or initiatives that delve more deeply into the main high-level sectors: power, transport, industry, buildings, and agriculture, forestry and other land-use (AFOLU). Whenever possible, this section also discusses issues in policy selection, design, and implementation that have been identified as more relevant in developing countries and emerging economies.

Overall, this section shows that national and subnational policies and institutions are one of the main factors determining the redirection and acceleration of technological innovation and low-emission technological change (Anadon et al. 2016b; Rogge and Reichardt 2016; Åhman et al. 2017; Anadón et al. 2017; Roberts et al. 2018) (*robust evidence, high agreement*). Both technology push (e.g., scientific training, research and development (R&D)) and demand pull (e.g., economic and fiscal support and regulatory policy instruments), as well as instruments promoting knowledge flows and especially research-firm technology transfer, can be part of the mix (*robust evidence, medium agreement*) (Sections 16.2 and 16.3).

Public R&D investments in energy and climate-related technologies have a positive impact on innovation outcomes (*medium evidence, high agreement*). The evidence on procurement is generally positive, but limited. The economic policy instruments that can be classified as market pull instruments when it comes to the competitiveness outcome (at least in the short term) is more mixed. The review of the literature in this section shows that market pull policy instruments had positive but also some negative impacts on outcomes in some instances on some aspects of competitiveness and distributional outcomes (*medium evidence, medium agreement*) (Peñasco et al. 2021). For several of them – such as carbon taxes or feed-in tariffs – the evidence of a positive impact on innovation is more consistent than the others. Evidence suggests that complementary policies or improved policy design can mitigate such short-term negative distributional impacts.

16.4.1 Overview of Policy Instruments for Climate Technology Innovation

Government policies can influence changes in technologies, as well as changes to the systems they support (Somanathan et al. 2014) (Chapter 13 and Sections 16.2 and 16.3).

Technology-push policy instruments stimulate innovation by increasing the supply of new knowledge through funding and performing research; increasing the supply of trained scientists and engineers which contribute to knowledge-generation and provide technological opportunities, which private firms can decide to commercialise (Mowery and Rosenberg 1979; Anadon and Holdren 2009; Nemet 2009b; Mazzucato 2013).

Governments can also stimulate technological change through demand-pull (or market-pull) instruments which support market creation or expansion and technology transfer, and thus promote learning by doing, economies of scale, and automation (Section 16.2). Demand-pull policy instruments include regulation, carbon prices, subsidies that reduce the cost of adoption, public procurement, and intellectual property regulation. Typically, technology push is especially important for early-stage technologies, characterised by higher uncertainty and lower appropriability (Section 16.2); demand-pull instruments become more relevant in the later stages of the innovation process (Mowery and Rosenberg 1979; Anadon and Holdren 2009; Nemet 2009b) (Section 16.2).

The second column of Table 16.8 summarises the set of policies shaping broader climate outcomes over the past few decades in many countries outlined in Chapter 13, Section 13.6, which groups them into economic and financial, regulatory, and soft instruments. Other policies, such as monetary, banking and trade policies, for instance, can also shape innovation, but most government action to shape energy has not focused on them. As Table 16.8 shows, this section discusses the set of policy instruments on innovation outcomes, or a subset of the 'Transformative Potential' criterion presented in Chapter 13, and thus complements the more general discussion presented there. Table 16.8 specifically prioritises the impact of the subset of policy instruments on innovation outcomes for which evidence is available. This focus is complemented by a discussion of the impact of the same policy instruments on competitiveness (a subcomponent of the economic effectiveness evaluation criterion) and on distributional outcomes. Many of the policy instrument types listed in Table 16.8 have been implemented or proposed to address the different types of market or systemic failures or bottlenecks described in Sections 16.2 and 16.3 (OECD 2011a).

Section 16.3 characterised technological innovation as a systemic, non-linear and dynamic process. Figure 16.1 below presents a stylised (and necessarily incomplete) view connecting the innovation process stages presented in Section 16.2, some of the key mechanisms in technology innovation systems, and some of the decarbonisation policy instruments that have been assessed in terms of their impact on technological innovation outcomes in Section 16.4.4. As noted in the caption and discussed in Section 16.4.4, regulatory policy instruments also shape the early stages of technology development.

Table 16.8 | Overview of policy instrument types covered in Chapter 13 and their correspondence to the subset of policy instrument types reviewed in Chapter 16 with a focus on innovation outcomes.

High-level categorisation	Lower-level policy instrument type in Chapter 13	Policy instrument types reviewed in Section 16.4 (for definitions see Peñasco et al. 2021)
Economic or financial policy instrument types	Research and development (R&D) investments	R&D investments (including demonstration) (Box 16.3)
	Subsidies for mitigation	Feed-in tariffs or premia (set administratively)
		Energy auctions
		Other public financing options (public investment banks, loans, loan guarantees)
	Emissions trading schemes	Emissions trading scheme
	Carbon taxes	Taxes/tax relief (including carbon taxes, energy taxes and congestion taxes)
	Government provision	Government provision (focus on innovation procurement)
	Removing fossil fuel subsidies	<i>Not covered</i>
	Border carbon adjustments	<i>Not covered</i>
Regulatory policy instrument types	Performance standards (including with tradeable credits)	Renewable obligations with tradeable green certificates
		Efficiency obligations with tradeable white certificates
		Clean energy or renewable portfolio standards (electricity)
		Building codes (building efficiency codes)
		Fuel efficiency standards
		Appliance efficiency standards
	Technology standards	<i>Not covered</i>
Soft policy instruments	Divestment and disclosure	<i>Not covered</i>
	Voluntary agreements (public voluntary programmes and negotiated agreements)	Voluntary agreements
		Energy labels

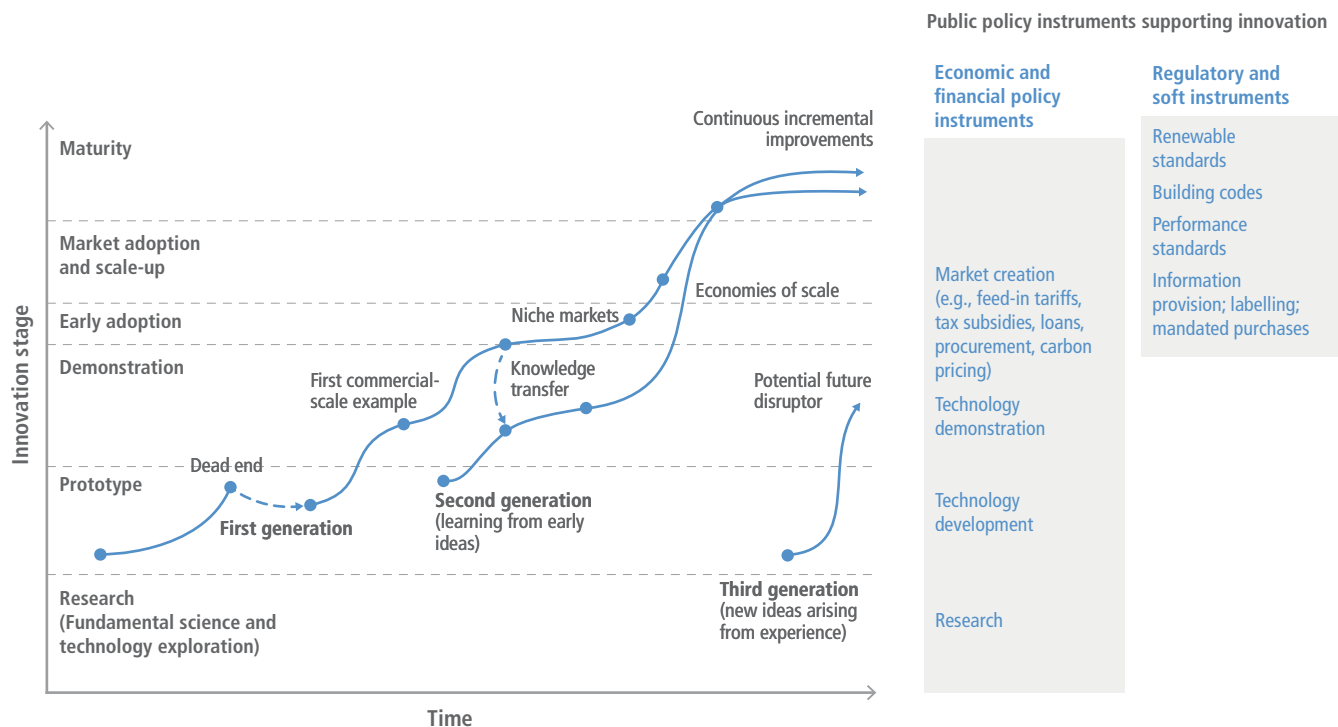

Figure 16.1 | Technology innovation process and the (illustrative) and role of different public policy instruments (on the right-hand side). Source: adapted from IEA (2020a). Note that, as shown in Section 16.4.4, demand-pull instruments in the regulatory instrument category, for instance, can also shape the early stages of the innovation process. Their position on the latter stages is highlighted in this figure because typically these instruments have been introduced in latter stages of the development of the technology.

16.4.2 The Drivers and Politics of National Policies for Climate Change Mitigation and Adaptation

Governments around the world implement innovation policies in the energy and climate space with the aim of simultaneously advancing environmental, industrial policy (or competitiveness), and security goals (Anadón 2012; Surana and Anadon 2015; Meckling et al. 2017; Matsuo and Schmidt 2019; Peñasco et al. 2021) (*medium evidence, medium agreement*). Co-benefits of policies shaping technological innovation in climate-related technologies, including competitiveness, health, and improved distributional impacts can be drivers of climate mitigation policy in the innovation sphere (Stokes and Warshaw 2017; Deng et al. 2018; Probst et al. 2020). For instance, this was the case for climate and air pollution policies with local content requirements for different types of renewable energy projects in places including China (Qiu and Anadon 2012; Lewis 2014), India (Behuria 2020), South Africa (Kuntze and Moerenhout 2012), and Canada (Genest 2014) (*robust evidence, medium agreement*).

The emergence of industries and support groups can lead to more sustained support for innovation policies (Meckling et al. 2015; Schmidt and Sewerin 2017; Stokes and Breetz 2018; Meckling 2019; Meckling and Nahm 2019; Schmid et al. 2020). Conversely, policies shaping technology innovation contribute to the creation and evolution of different stakeholder groups (*robust evidence, high agreement*). Most of the literature on the role of the politics and interest groups has focused on renewable energy

technologies, although there is some work on heating in buildings (Wesche et al. 2019).

As novel technologies become cost-competitive, opposition of incumbents usually grows, as well as the dangers of lock-in that can be posed by the new winner. Addressing this involves adapting policy (*robust evidence, high agreement*).

Three phases of politics in the development of policies to meet climate and industrial objectives can be identified, at the top, the middle and the bottom of the experience curve (Breetz et al. 2018) (see also Figure 16.1, and Geels 2002). In the first phase of 'niche market diffusion', the politics of more sustained support for a technology or set of technologies become possible after a group of economic winners and 'clean energy constituencies' are created (Meckling et al. 2015). When technologies grow out of the niche (second phase), they pose a more serious competition to incumbents who may become more vocal opponents of additional support for innovation in the competing technologies (Geels 2014; Stokes 2016). In a third phase, path-dependence in policymaking and lock-in in institutions need to change to accommodate new infrastructure, the integration of technologies, the emergence of complementary technologies and of new regulatory regimes (Levin et al. 2012; Aklin and Urpelainen 2013).

16.4.3 Indicators to Assess the Innovation, Competitiveness and Distributional Outcomes of Policy Instruments

If policy instruments are created to (at least partly) shape innovation for systemic transitions to a zero-carbon future, they also need to be evaluated on their impact on the whole socio-technical system (Neij and Åstrand 2006) and a wide range of goals, including distributional impacts and competitiveness and jobs (Stern 2007; Peñasco et al. 2021). Given this and the current policy focus on green recovery and green industrial policy, we assess impacts on competitiveness and equity, although we primarily focus on innovation outcomes. Table 16.9 lists the selected set of indicators used to assess the impact of the policy instrument types covered in the right-hand column in Table 16.8. The table does not include technology diffusion or deployment because these are covered in the technological effectiveness evaluation criterion in Chapter 13. As noted in section 16.2, it is very difficult to measure or fully understand innovation with one or even several indicators. In addition, all indicators have strengths and weaknesses, and may be more relevant in some countries and sectors than in others. The literature assessing the impact of different policy instruments on innovation often covers just one of the various indicators listed in the second column of Table 16.9.

16.4.4 Assessment of Innovation and Other Impacts of Innovation Policy Instruments

While it is very difficult to attribute a causal relationship between a particular policy instrument implementation and different innovation indicators, given the complexity of the innovation system (Section 16.3), there is a large volume of quantitative and qualitative literature aiming to identify such an impact.

16.4.4.1 Assessment of the Impact on Innovation of Technology Push Policy Instruments: Public RD&D Investments, Other R&D Incentives and Public Procurement

Economic and direct investment policy instrument types are typically associated with a direct focus on technological innovation: research and development (R&D) grants, R&D tax credits, prizes, national laboratories, technology incubators (including support for business development, plans), novel direct funding instruments

(e.g., Advanced Research Projects Agency–Energy (ARPA-E)), and innovation procurement.

Public research, development and demonstration (RD&D) investments have been found to have a positive impact on different innovation in energy- and climate-related technologies (*robust evidence, high agreement*), but the assessment relies almost entirely on evidence from industrialised countries. Out of 17 publications focusing on this assessment, only three found no relationship between R&D funding and innovation metrics (Doblinger et al. 2019; Goldstein et al. 2020; Peñasco et al. 2021). Sixteen of them used *ex post* quantitative methods, and one relied on theoretical *ex ante* assessment; only two of them included some non-industrialised countries, with one being the theoretical analysis. The evidence available does not point to public R&D funding for climate-related technologies crowding out private R&D (an important driver of innovation) but instead crowding it in. Box 16.6 summarises the evidence available of the impact of ARPA-E (a public institution created in the USA in 2009 to allocate public R&D funding in energy) on innovation and competitiveness outcomes. Another institution supporting energy R&D that is the subject of much interest is the institutions of the Fraunhofer Society.

No evidence has been found regarding the specific impact of R&D tax credits on climate mitigation or adaptation technologies, but it is worth noting that, generally speaking, R&D tax credits are found to incentivise innovation in firms, with a greater impact on small and medium firms (OECD 2020). This is consistent with the fact that most of the evidence on the positive impact of public R&D support schemes covers small and medium firms (Howell 2017; Doblinger et al. 2019; Goldstein et al. 2020). Although there is a high level of agreement in the literature regarding the impact of R&D investments on innovation outcomes in climate-related technologies, it is important to note that this evidence comes from industrialised countries. This does not mean that public R&D investments in energy have been found to have no impact on developing countries innovation or competitiveness outcomes, but rather that we were not able to find such studies focussing on developing countries.

Overall, public procurement has high potential to incentivise innovation in climate technologies, but the evidence is mixed, particularly in developing countries (*limited evidence, medium agreement*). Public procurement accounted for 13% of gross domestic product (GDP) in OECD in 2013 and much more in some

Table 16.9 | Outcomes (first row) and indicators (second row) to evaluate the impact of policies shaping innovation to foster carbon neutral economies.

Sources: innovation outcomes indicators are sourced from Del Rio and Cerdá (2014), Grubb et al. (2021) and Peñasco et al. (2021); the indicators under the competitiveness and distributional effects criteria are sourced from Peñasco et al. (2021).

Policy instrument Outcomes	Innovation (Part of Chapter 13 'Transformative potential' evaluation criterion)	Competitiveness (Part of Chapter 13 'Economic effectiveness' evaluation criterion)	Distributional impacts (Defined in the same way as in Chapter 13)
Examples of indicators used for each outcome in the literature	R&D investments, cost improvements, learning rates, patents, publications, reductions in abatement costs, energy efficiency improvements, other performance characteristics, firms reporting carbon saving innovation	Industry creation, net job creation, export of renewable energy technology equipment, economic growth (GNP, GDP), productivity, other investments	Level and incidence of support costs, change in spending on electricity as a percentage of total household spending, participation of different stakeholders, international equity (e.g., tCO ₂ -eq per capita), unequal access between large vs. small producers or firms

Box 16.5 | Green Public Procurement in The Netherlands

In 2005, the Dutch national government acknowledged a move in the House of Representatives to utilise their annual spending power to promote the market for sustainable goods and services, as well as to act as a role model. Hence, a policy for environmentally-friendly procurement was developed and implemented across the national, local and provincial governments. Subsequently, sustainable public procurement has expanded into a multidimensional policy in The Netherlands, accommodating policies on green public procurement, bio-based public procurement, international social criteria, social return on investment, innovation-oriented public procurement and circular economy.

The Green Public Procurement (GPP) policy is targeted at minimising the negative impacts of production and consumption on the nature environment (Melissen and Reinders 2012; Cerutti et al. 2016). It includes a wide range of environmental criteria for different product groups that public organisations frequently procure, such as office equipment, uniforms, road works and catering. There are 45 product groups (Melissen and Reinders, 2012) and six product clusters as part of the government's purchasing in terms of sustainability (PIANOo Expertisecentrum 2020). The six product clusters are: i) automation and telecommunications; ii) energy; iii) ground, road and hydraulic engineering; iv) office facilities and services; v) office buildings; and vi) transport (PIANOo Expertisecentrum 2020). The GPP 2020 Tender Implementation Plan spells out the terms and conditions for green public procurement. Some of these are confidential documents and are not shared online. Others are available for download. The tender implementation plan for The Netherlands is available on <https://gpp2020.eu/low-carbon-tenders/open-tenders/>. One of the important scenarios is that the public procurers need the details of Life Cycle Analysis (LCA) carried out in a tool called DuboCalc, which calculates the environmental impacts of the materials and methods of an infrastructural projects. GPP 2020 has reported that three million tonnes of CO₂ would be saved in The Netherlands alone if all Dutch public authorities applied the national Sustainable Public Procurement Criteria.

Research has been carried out to determine the prime mover for implementing Green Public Procurement. An online survey was administered among public procurement officers who subscribed to the newsletters of two Dutch associations that provide advice and training to public procurers. This yielded a sample size of more than 200 (Grandia and Voncken 2019). The first association is called Nevi which is the only organisation in The Netherlands that offers certified procurement training programmes. The second association is called PIANOo which is a public procurement expertise centre paid by the Dutch national government to bring together relevant information regarding public procurement and provide public procurers with useful tools through their websites, workshops, meetings and annual conferences. The data from the survey was then analysed using structural equations modelling (SEM) and the results show that ability, motivation and opportunities affect the implementation of GPP. Particularly, opportunity was found to affect GPP, innovation-oriented public procurement and the circular economy, but not the other types of public procurement.

emerging and developing economies (Baron 2016). Its main goal is to acquire products or services to improve public services, infrastructures and facilities and, in some cases, to also incentivise innovation. It is important to implement several steps in the public procurement procedure to improve transparency, minimise waste, fraud and corruption of public fund. These steps range from the assessment of a need, issuance of a tender, to the monitoring of delivery of the good or service. Box 16.5 outlines a public procurement programme that was implemented in The Netherlands in 2005 with a focus on green technologies. In spite of the fact that green procurement policies have been implemented, the literature assessing the innovation impact of public procurement programmes is relatively limited, and suggests either a positive impact or no impact (Alvarez and Rubio 2015; Baron 2016; Fernández-Sastre and Montalvo-Quizhpi 2019; Peñasco et al. 2021). The majority of cases where the impact is positive are analyses of industrialised countries, while no impact emerges in the case of a developing country (Ecuador). More empirical research in both developing and developed countries is needed to understand the impact of public procurement, which has the potential to support the achievement of other societal challenges (Edler and Georgiou 2007; Henderson and Newell 2011; Baron 2016; ICLEI 2018).

16.4.4.2 Assessment of the Impact on Competitiveness of Technology Push Policy Instruments: Public RD&D Investments, Other R&D Incentives and Public Procurement

Public R&D investments in the energy, renewables, and environment space are generally associated with positive impacts on industrial development or 'competitiveness outcome' (*robust evidence, medium agreement*). In a number of cases, negligible or negative impacts emerge (Doblinger et al. 2019; Goldstein et al. 2020; Peñasco et al. 2021). The majority of the 15 analyses rely on *ex post* quantitative methods, while only four use *ex ante* modelling approaches. Also, in this case, the vast majority of the evidence is from industrialised countries.

There is limited and mixed evidence regarding the (positive or negative) impact of public procurement for low-carbon or climate technologies in developed countries (*limited evidence, low agreement*), and none from developing countries. All of the four evaluations identified in the Peñasco et al. (2021) review relied on qualitative methods. One found a positive impact, another a negative impact and two others found no impact. All of the studies covered European country experiences.

R&D and procurement policies have a positive impact on distributional outcomes (*limited evidence, high agreement*). Peñasco et al. (2021) identify three evaluations of the impact of RD&D funding on distributional outcomes (two using quantitative methods and one *ex ante* theoretical methods) and one of procurement on distributional outcomes (relying on qualitative analysis).

16.4.4.3 Emerging Insights on Different Public R&D and Demonstration Funding Schemes

The ability of a given R&D policy instrument to impact innovation and competitiveness depends to some extent on policy design features (*limited evidence, high agreement*). As discussed in Section 16.4.4.4, this is not unique to R&D funding. Most of these assessments use a limited number of indicators (e.g., patents and publications and follow-on private financing, firm growth and survival, respectively), and are focused on the energy sector, and on the USA and other industrialised countries. Extrapolating to emerging economies and low-income countries is difficult. There is no evidence on the impact of different ways of allocating public energy R&D investments in the context of developing countries.

Block funding, which tends to be more flexible, can lead to research that is more productive or novel, but there are other factors that can affect the extent to which block funding can lead to more or less novel outcomes (*limited evidence, medium agreement*). Research on national research laboratories, which conduct at least 30% of all research in 68 countries around the world (Anadon et al. 2016a), are a widespread mechanism to carry out public R&D and allocate funds, but assessments of their performance is limited to developed countries. R&D priorities are also guided by institutions, and research focused on general technology innovation policy finds that institutions often do not embody the goals of the poor or marginalised (Anadon et al. 2016b).

In the case of the US Department of Energy, block funding that can be quickly allocated to novel projects (such as that allocated to National Labs as part of the Laboratory Directed Research and Development funding) has been found to be associated with improved innovation indicators (Anadon et al. 2016a). Research in Japan on R&D funding in general (not for climate-related technologies) however, indicates that R&D funds allocated competitively result in higher novelty for 'high status' (the term used in the paper to refer to senior male researchers), while block funding was associated with research of higher novelty for 'lower status' researchers (e.g., junior female researchers) (Wang et al. 2018).

Box 16.6 | ARPA-E – A Novel R&D Funding Allocation Mechanism Focused on an Energy Mission

One approach for allocating public R&D funds in energy involves relying on active programme managers and having clear technology development missions that focus on high-risk high-reward areas and projects. This approach can be exemplified by a relatively new energy R&D funding agency in the USA, the Advanced Research Projects Agency for Energy (ARPA-E). This agency was created in 2009 and it was modelled on the experience of Defense Advanced Research Projects Agency (DARPA) – a US government agency funding high-risk, high-reward research in defence-related areas (Bonvillian and Van Atta 2011; US National Academies of Sciences Engineering and Medicine 2017; Bonvillian 2018). DARPA programme managers had a lot of discretion for making decisions about funding projects, but since energy R&D funding is usually more politically vulnerable than defence R&D funding, the ARPA-E model involved programme managers requesting external review as an informational input (Azoulay et al. 2019).

As for DARPA, ARPA-E programme managers use an active management approach that involves empowering programme managers to make decisions about funding allocation, milestones and goals. ARPA-E managers also differ from other R&D allocation mechanisms in that ARPA-E staff retain some control on the funded projects after the allocation of funds. As argued by Azoulay et al. (2019), even though this relative control over the project can result in a reduction in the flexibility of funded researchers, some 'exploration' happens at the programme manager level.

Research on ARPA-E also sheds light on the process of project selection, or how programme managers decide what projects to fund. Programme managers do not just follow the rankings of peer reviewers (sometimes projects with very disparate rankings were funded) and in many cases programme managers reported using information from review comments instead of the rankings (Goldstein and Kearney 2020). Azoulay et al. (2019) suggest that, if expert disagreement is a useful proxy for uncertainty in research, then the use of individual discretion in ARPA-E would result in a portfolio of projects with a higher level of uncertainty, as defined by disagreement among reviewers. Moreover, under the premise that uncertainty is a corollary to novelty, individual discretion is an antidote to novelty bias in peer review.

While innovation is notoriously hard to track and, particularly for emerging technologies, it can take a lot of time to assess, early analysis has shown that this mission-orientation and more 'actively managed' R&D funding programme may yield greater innovation patenting outcomes than other US energy R&D funding programmes, and a greater or similar rate of academic publications when compared to other public funding agencies in energy in the USA, ranging from the Office of Science, the more applied Office of Energy Efficiency and Renewable Energy, or the small grants office (US National Academies of Sciences Engineering and Medicine 2017; Goldstein and

Box 16.6 (continued)

Narayanamurti 2018). In addition, research analysing the first cohort of cleantech start-ups has found that start-ups supported by ARPA-E had more innovative outcomes when compared to those that had applied but not received funding, with others that had not received any government support, and with others that had received other types of government R&D support (Goldstein et al. 2020). Overall, the mission-oriented ARPA-E approach has been successful in the USA when it comes to innovation outcomes. The extent to which it can yield the same outcomes in other geographies with different innovation and financing environments remains unknown. (*limited evidence, high agreement*).

Public financing for R&D and research collaboration in the energy sector is important for small firms, at least in industrialised countries, and it does not seem to crowd out private investment in R&D (*medium evidence, high agreement*). Small US and UK firms accrue more patents and financing when provided with cash incentives for R&D in the form of grants (Howell 2017; Pless 2019). US cleantech start-ups which partner with government partners for joint technology development or licensing partnerships accrue more patents and follow-on financing (Doblinger et al. 2019).

Overall, the body of literature on public R&D funding design in energy- and climate-related technologies provides some high-level guidance on how to make the most of these direct RD&D investments in energy technologies in the climate change mitigation space, including: giving researchers and technical experts autonomy and influence over funding decisions; incorporating technology transfer in research organisations; focusing demonstration projects on learning; incentivising international collaboration in energy research; adopting an adaptive learning strategy; and making funding stable and predictable (Narayanamurti et al. 2009; Narayanamurti and Odumosu 2016; Chan et al. 2017) (*medium evidence, high agreement*).

Without carefully designed public funding for demonstration efforts, often in a cost-shared manner with industry, the experimentation at larger scales needed for more novel technologies needed for climate change mitigation may not take place. (*medium evidence, high agreement*). Government funding, specifically for technology demonstration projects, for RD&D in energy technologies, plays a crucial supporting role (Section 16.2.1). Governments can facilitate knowledge spillovers between firms, between countries, and between technologies (Cohen et al. 2002; Baudry and Bonnet 2019) (Section 16.2).

16.4.4.4 Assessment of the Impact on Innovation and on Competitiveness and Distributional Outcomes of Market Pull Policy Instruments

Demand-pull policies such as tradeable green certificates, taxes, or auctions, are essential to support scaling-up efforts (Remer and Mattos 2003; Wilson 2012; Nahm and Steinfeld 2014). Just as for R&D investments, research has indicated that effective demand pull needs to be credible, durable, and aligned with other policies (Nemet et al. 2017) and that the effectiveness of different demand-pull instruments depends on policy design (del Río and Kiefer 2021).

Historical analyses of the relative importance of demand pull and technology push are clear: both are needed to provide robust incentives for investment in innovation. Interactions between them are central as their combination enables innovators to connect a technical opportunity with a market opportunity (Freeman 1995; Jacobsson et al. 2004; Grubler and Wilson 2013). It is important to note that these market pull policies are often put in place primarily to meet security and/or environmental goals, although innovation and competitiveness are sometimes also pursued explicitly.

Emissions trading schemes

Overall evidence suggests that the emissions trading schemes, as currently designed, have not significantly contributed to innovation outcomes (*medium evidence, medium/high agreement*).

Penasco et al. (2021) review 20 evaluations: eight identified a positive impact (although in at least two cases, the paper indicated that the impact was small or negligible); 11 no impact; and one was associated with a negative impact on innovation indicators. The studies that found no impact and the studies that found some impact covered all three methods (quantitative *ex post*, qualitative and theoretical and *ex ante* analysis). Another review focused only on empirical studies (mainly quantitative but also qualitative), covered a slightly longer period and identified 19 studies (15 using quantitative methods) (Lilliestam et al. 2021). With a narrower set of indicators of innovation, they concluded that there was very little empirical evidence linking innovation with the emissions trading schemes studied to date (Lilliestam et al. 2021). This review focused mainly on papers evaluating the earlier stages of the European Emissions Trading Scheme, which featured relatively low carbon dioxide prices, and covered a small set of firms, showing that carbon pricing policy design is an important determinant of innovation outcomes. Combining both reviews, there are a total of 27 individual studies, some of them providing mixed evidence of impact, and 23 of them suggest there was no impact or that (in a couple of cases) it was small. It is important to note that some researchers note that, for particular subsectors and actors, emissions trading schemes have had an impact on patenting trends (Calel and Dechezleprêtre 2016). Overall the expectation is that higher prices and coverage would result in higher impacts and that, over time, the impact on innovation would grow.

Carbon and environmental taxes

The impact of carbon taxes on innovation outcomes is more positive than that for emissions trading schemes, but the evidence is more limited (*limited evidence, medium agreement*). Assessments of their impact on innovation metrics have been very limited, with only four studies (three quantitative and one *ex ante*). Three of the studies found a positive impact of carbon taxes on innovation outcomes, and one found no impact (Peñasco et al. 2021).

Depending on the design (including the value and coverage of the tax), carbon taxes can either have positive, negative or null impact on competitiveness and distributional outcomes (*medium evidence, medium agreement*). The evidence on the impact of carbon taxes on competitiveness is significant (a total of 27 evaluations) and mixed, with six of them reporting some positive impacts, 10 reporting no impact, and 11 reporting negative impacts (so 59% were not associated with negative impacts). Most of the evaluations reporting negative impacts were theoretical assessments, and only three *ex post* quantitative analysis (Peñasco et al. 2021). Twenty-four evaluations covered distributional impacts of carbon taxes and other environmental taxes, the majority (15) found the existence of some negative distributional impacts, six found positive impacts, and three found no distributional impacts. Differences in the assessment results stem from the design of the taxes (Peñasco et al. 2021). It is important to note that, once again, the evidence comes from industrialised countries and emerging economies.

Feed-in-tariffs

Many factors affect the impacts of feed-in tariffs (FITs) on outcomes other than innovation (*robust evidence, high agreement*). While FITs have been generally associated with positive innovation outcomes, some of the differences found in the literature may arise from differences in the evaluation method (Peñasco et al. 2021) or differences in policy design (e.g., the level and the rate of decrease of the tariff) (Hoppmann et al. 2014), the policy mixes (Rogge et al. 2017), the technologies targeted and their stage of development (Huenteler et al. 2016b), and the geographical and temporal context of where the policy was put in place (Section 16.3). Research has also found that, particularly for less mature technologies, a higher technology specificity in the design of FITs is associated with more innovation (Del Río 2012). FITs yield better results if they account for the specificities of the country; or else, the technology and the policy could result in negative distributional and (to a lesser extent) competitiveness impacts. Meckling et al. (2017) indicate that an 'enduring challenge' of technology-specific industrial policy such as some FITs is to avoid locking in suboptimal clean technologies – a challenge which, among other options, could be overcome with targeted niche procurement for next-generation technologies. Other authors have cautioned that the move from renewable FITs to auctions may favour existing PVs (e.g., polysilicon) over more novel solar power technologies (Sivaram 2018b) such as thin-film PV, amorphous PV, and perovskites.

Policy design, policy mixes, and domestic capacity and infrastructure are important factors determining the extent to which economic policy

instruments in industrialised countries and emerging economies can also lead to positive (or at least not negative) competitiveness outcomes and distributional outcomes (*medium evidence, medium agreement*) (Section 16.3). Prioritising low-cost energy generation in the design of FIT schemes can result in a lower focus of innovation efforts on more novel technologies and greater barriers to incumbents in less mature technologies (Hoppmann et al. 2013). Similarly, case study research from Mexico and South Africa indicates that focusing on low-cost renewable energy generation can only result in a greater reliance on existing foreign value chains and capital, and thus in lower or negative impacts on domestic competitiveness. In other words, some approaches can hinder the development of the local capabilities that could result in greater long-term benefits domestically (Matsuo and Schmidt 2019). Evidence for developing countries indicates that local and absorptive capacity also play an important role, in particular, on the ability of policies to contribute to competitiveness or industrial policy goals (Binz and Anadon 2018). Research comparing China's and India's policies and outcomes on wind energy also suggest that policy durability and systemic approaches can affect industrial outcomes (Surana and Anadon 2015).

Energy auctions

The evidence of the impact of renewable energy auctions on innovation outcomes is very small and provides mixed results (*limited evidence, low agreement*). Out of six evaluations, three identify positive impacts, two no impacts, and one negative impacts. All of the evaluations but one were qualitative or theoretical, and the quantitative assessment indicated no impact (Peñasco et al. 2021). There is more evidence covering emerging economies analysing the impacts of auctions when compared to other policy instrument types. For example, there is work comparing the approaches to renewable energy auctions in South Africa and Denmark (Toke 2015) finding a positive impact on the latter stages of innovation (mainly deployment), and broader work on auctions covering OECD countries as well as Brazil, South Africa and China not finding a significant impact on innovation (Wigand et al. 2016). Work comparing renewable energy auctions in different countries in South America generally finds a positive impact on innovation outcomes (Mastropietro et al. 2014). The body of evidence on the impact of auctions on competitiveness is also limited (six evaluations) and indicates negative outcomes of renewable auctions of competitiveness (*limited evidence, low agreement*). As with other policies, the design of the auctions can affect innovation outcomes (del Río and Kiefer 2021). Only two studies investigated distributional outcomes, and both were negative.

Other financial instruments

There is no explicit literature on the ability of green public banks, and targeted loans, and loan guarantees to lead to upstream innovation investments and activities, although there is evidence on their role in deployment (Geddes et al. 2018). This notwithstanding, the key role of these institutions is in the innovation system (OECD 2015b; Geddes et al. 2018) (Sections 16.2.1 and 16.3) and the belief that they can de-risk scale-up and the testing of business models (Geddes et al. 2018; Probst et al. 2021) (Chapter 17).

Renewable obligations with tradeable green certificates

There is mixed evidence of the impact of tradeable green certificates (TGCs) on innovation (*limited evidence, low agreement*) and competitiveness (*limited evidence, low agreement*). Out of the 11 evaluations in Peñasco et al. (2021), six found no impact, two a positive impact, and three a negative impact. All of them used a qualitative research approach. Of the six studies focusing on competitiveness outcomes, three conclude that TGCs have had no impact on competitiveness, while two indicate a negative impact and one a positive impact. Only one of the studies was quantitative, and did not identify an impact on competitiveness.

TGCs are associated with the existence of negative distributional impacts in most applications (*medium evidence, high agreement*). Ten out of 12 studies identify the existence of some negative impacts. All but one of these studies (which focused on India) are based on analysis of policies implemented in industrialised countries.

Clean energy and renewable portfolio standards

The impact of renewable portfolio standards without tradeable credits on innovation outcomes is negligible or very small (*medium evidence, medium agreement*). Out of the nine studies, seven reported no impact on innovation outcomes and two a positive impact (Peñasco et al. 2021). Most of these papers focused on patenting and private R&D innovation indicators and not cost reductions. Impact on competitiveness is found to be negligible or positive (*limited evidence, medium agreement*). Out of eight evaluations, five report a positive impact and three a negligible impact; only two are quantitative studies (Peñasco et al. 2021). Negative distributional impacts from renewable portfolio standards can emerge in some cases (*limited evidence, low agreement*). Out of eight evaluations, four identified positive impacts, and four negative impacts; all of the studies identifying a positive impact were theoretical. There are efforts focused on clean energy portfolio standards which include technologies beyond renewables.

Efficiency obligations with tradeable credits

The impact of tradeable white certificates in innovation is largely positive, but the evidence is limited (*limited evidence, medium/high agreement*). Out of four evaluations, only one of which was quantitative, three report a positive impact and one reports no impact (Peñasco et al. 2021). The impact of white certificates on competitiveness is positive (*limited evidence, high agreement*) while the impact on distributional outcomes is very mixed (*limited evidence, low agreement*). Two theoretical studies report positive competitiveness impacts. Out of 11 evaluations of distributional outcomes, eight rely on theoretical *ex ante* approaches. Of the 11 evaluations: seven reported positive impacts (four of them using theoretical methods); three indicated negative impacts (using theoretical methods); and one reported no impact.

Building codes

There is evidence of the impact of building codes on innovation outcomes (Peñasco et al. 2021). Only two studies assessed competitiveness impacts (one identified positive impacts and one negligible ones) and three studies identified distributional impacts, all positive.

Overall, the evidence on the impact of the market pull policy instruments covered in Section 16.4.4.4 when it comes to the competitiveness outcome (at least in the short term) is more mixed. For some of them, the evidence of a positive impact on innovation is more consistent than the others (for carbon taxes or FITs, for example). Peñasco et al. (2021) found that the disagreements in the evidence regarding the positive, negative or no impact of a policy on competitiveness or distributional outcomes can often be explained by differences in policy design, differences in geographical or temporal context (since the review included evidence from countries from all over the world), or on how policy mixes may have affected the ability of the research design of the underlying papers to separate the impact of the policy under consideration from the others.

16.4.4.5 Assessment of the Impact on Innovation, Competitiveness and Distributional Outcomes of Regulatory Policy Instruments Targeting Efficiency Improvements

There is medium evidence that the introduction of flexible, performance-based environmental regulation on energy efficiency in general (e.g., efficiency standards) can stimulate innovative responses in firms (Ambec et al. 2013; Popp 2019) (*medium evidence, high agreement*). Evidence comes from both observational studies that examine patenting, R&D or technological responses to regulatory interventions, and from surveys and qualitative case studies in which firms report regulatory compliance as a driving force for the introduction of environmentally-beneficial innovations (Grubb et al. 2021). While the literature examining the impact of environmental regulation on innovation is large, there have been fewer studies on the innovation effects of minimum energy or emissions performance regulations specifically relating to climate mitigation. We discuss in turn two types of efficiency regulations: on vehicles, and on appliances.

Relationship between automotive efficiency regulations and innovation

The announcement, introduction and tightening of vehicle fleet efficiency or greenhouse gas (GHG) emission standards either at the national or sub-national level positively impacts innovation as measured by patents (Barbieri 2015) or vehicle characteristics (Knittel 2011; Kiso 2019) as summarised in a review by Grubb et al. (2021). Detailed studies on the innovation effects of national pollutant (rather than energy) regulations on automotive innovation also indicate that introducing or tightening performance standards has driven technological change (Lee et al. 2010). Some studies in the USA that examine periods in which little regulatory change took place have found that the effects of performance standards on fuel economy have been small (Knittel 2011) or not significant relative

to the innovation effects of prices (Crabb and Johnson 2010). This is at least in part because ongoing efficiency improvements during this period were offset by increases in other product attributes. For example, a study by Knittel (2011) observed that size and power increased without a corresponding increase in fuel consumption. It has also been observed that regulatory design may introduce distortions that affect automotive innovation choices: in particular, fuel economy standards based on weight classes have been observed to distort light-weighting strategies for fuel efficiency in both China (Hao et al. 2016) and Japan (Ito and Saltee 2018).

A number of studies have focused on the impacts of a sub-national technology-forcing policy: the California Zero Emission Vehicle (ZEV) mandate. When it was introduced in 1990, this policy required automotive firms to ensure that 2% of the vehicles they sold in 1998 would be zero-emission. In the years immediately after introduction of the policy, automotive firms reported that it was a significant stimulus to their R&D activity in electric vehicles (Brown et al. 1995). Quantitative evidence examining patents and prototypes has indicated that the stringency of the policy was a significant factor in stimulating innovation, though this was, in part, dependent on firm strategy (Sierchula and Nemet 2015). As for the previous instruments, most of the evidence comes from industrialised countries, and additional research on other countries would be beneficial.

Relationship between appliance efficiency standards and innovation

Regulation-driven deployment of existing technologies can generate innovation in those technologies through learning by- doing, induced R&D and other mechanisms, although not in all cases (*medium evidence, medium agreement*) (Grubb et al. 2021). The introduction or tightening of minimum energy performance standards for appliances (and for buildings, in Noailly (2012)) have driven innovation responses, using direct measures of product attributes (Newell et al. 1999) and patents (Noailly 2012; Kim and Brown 2019), though not all studies have found a significant relationship (Girod et al. 2017). There is also evidence of a correlation between regulation-driven deployment of energy-efficient products with accelerated learning in those technologies (Van Buskirk et al. 2014; Wei et al. 2017).

In addition to observational studies, evidence on the relationship between innovation and regulation comes from surveys in which respondents are asked whether they have engaged in innovation leading to energy saving or reduced GHG emissions, and what the motivations were for such innovation. Survey evidence has found that expected or current regulation can drive both R&D investment and decisions to adopt or introduce innovations that reduce energy consumption or CO₂ emissions (Horbach et al. 2012; Grubb et al. 2021). Survey-based studies, however, tend not to specify the type of regulation.

Competitiveness and distributional impacts associated with vehicles and appliance performance standards

Minimum energy performance standards and appliance standards have been known to result in negative distributional impacts (*limited evidence, medium/high agreement*). Several studies focused

on the USA have highlighted that minimum energy performance standards for vehicles tend to be regressive, with poorer households disproportionately affected (Jacobsen 2013; Levinson 2019), particularly when second-hand vehicles are taken into account (Davis and Knittel 2019). Similar arguments, though with less evidence, have been made for appliance standards (Sutherland 2006).

Overall, the extent to which regulations in energy efficiency result in positive or negative competitiveness impacts in firms is mixed (*limited evidence, high disagreement*). A meta-analysis of 107 studies, of which 13 focused on regulations relating to energy consumption or GHG emissions, found that around half showed that regulations resulted in competitiveness impacts, while half did not (Cohen and Tubb 2018). Cohen and Tubb (2018) also found that studies examining performance-based regulations were less likely to find positive competitiveness impacts than those that examined market-based instruments.

Insights into causal mechanisms and co-evolutionary dynamics from case studies on efficiency regulations

While most of the literature addresses the extent to which regulation can induce innovation, a number of case studies highlight that innovation can also influence regulation, as the costs of imposing regulation are reduced and political interests emerge that seek to exploit competitive advantages conferred by successfully developing energy-efficient or low-carbon technologies (*medium evidence, high agreement*). Case studies map the causal mechanisms relating regulations and innovation responses in specific firms or industries (Gann et al. 1998; Kemp 2005; Ruby 2015; Wesseling et al. 2015).

16.4.4.6 Assessment of the Impact on Innovation and on Competitiveness and Distributional Outcomes of Soft Instruments

Energy labels and innovation

The literature specifically focusing on the impacts of labels is very limited and indicates positive outcomes (*limited evidence, high agreement*). Energy labels may accompany a minimum energy performance standard, and the outcomes of these policies are often combined in literature (IEA 2015). But again, given the limited evidence, more research is needed. Although there are many studies on energy efficiency more broadly and for both standards and labels, only eight studies specifically focus on labels. Furthermore, seven of them report positive outcomes and one negative outcomes. Six of the studies used qualitative methods mentioning the impacts of labelling on the development of new products (Wiel et al. 2006). Research specifically comparing voluntary labels with other mechanisms found a significant and positive relationship between labels and the number of energy-efficient inventions (Girod et al. 2017). More research is needed, especially in developing countries, that have extensive labelling programmes in place, and also with quantitative methods, to develop evidence on the impacts of labelling on innovation. Box 16.7 discusses an example of a combination of policy instruments in China including labelling, sale bans and financial support.

Box 16.7 | China Energy Labelling Policies, Combined with Sale Bans and Financial Subsidies

From 1970 to 2001, China was able to significantly limit energy demand growth through energy-efficiency programmes. Energy use per unit of gross domestic product (GDP) declined by approximately 5% yr⁻¹ during this period. However, between 2002 and 2005, energy demand per unit of GDP increased on average by 3.8% yr⁻¹. To curb this energy growth, in 2005, the Chinese government announced a mandatory goal of 20% reduction of energy intensity between 2006 and 2010 (Zhou et al. 2010; Lo 2014).

An energy labelling system was passed in 2004. It requires manufacturers to provide information about the efficiency of their electrical appliances to consumers. From 2004 to 2010, 23 electrical appliances (including refrigerators, air conditioners and flat-screen TVs) being labelled as energy efficient with five different grades – grade 1 being the most energy efficient and grade 5 the least efficient. Any appliances with an efficiency grade higher than 5 cannot be sold in the market.

In addition to providing information to consumers, the National Development and Reform Commission, (which was in charge of designing the policies), and the Ministry of Finance launched in 2009 the ‘energy-saving products and civilian-benefiting project’ (Zhan et al. 2011). It covered air conditioners, refrigerators, flat panel televisions, washing machines, electrical efficient lighting, energy saving and new energy vehicles with the energy grades at 1 or 2. The project also included financial subsidies for the enterprises producing these products. The standard design of these financial subsidies involved the government paying for the price difference of energy-efficient products and general products. The manufacturers that produce the energy-efficient products receive financial subsidies directly from the government (Z. Wang et al. 2017).

Before 2008, the market share of grade 1 and grade 2 air conditioners was about 5%, and about 70% of all air conditioners were grade 5 (the most inefficient). Driven by the financial subsidies, the selling price of the highly efficient air conditioners became competitive with that of the general air conditioners. Hence, the sales of energy-efficient air conditioners increased substantially, making the market share of grade 1 and 2 air conditioners about 80% in 2010 (Z. Wang et al. 2017). According to the information from China’s National Institute of Standardization, the energy label system saved more than 1.5 hundred billion kWh power between 2005 and March 2010, equivalent to more than 60 million tonnes of standard coal, 1.4 billion tonnes of carbon dioxide emissions, and 60 tonnes of sulphur dioxide emissions (Zhan et al. 2011), which significantly contributed to energy saving goals of China’s 11th Five-Year Plan.

Voluntary approaches and innovation

Voluntary approaches have a largely positive impact on innovation for those that choose to participate (*robust evidence, medium agreement*). Research on voluntary approaches focuses on firms adopting voluntary environmental management systems that can be certified based on standards of the widely adopted International Organization for Standardization (ISO 14001 – standard for environmental management) or the European Union’s Eco-Management and Auditing Scheme (EMAS), which is partly mandatory. Out of 16 analyses: 70% report positive innovation outcomes in terms of patents, products or processes; 17% report negligible impacts; and 13% report negative impacts. Positive innovation outcomes have been linked to firms’ internal resource management practices and were found to be strengthened in firms with mature environmental management systems and in the presence of other environmental regulations (Inoue et al. 2013; He and Shen 2019; Li et al. 2019a). Overall, studies are concentrated in a few countries that do not fully capture where environmental management systems have been actually adopted (Boiral et al. 2018). There is a need for research in analyses of such instruments in emerging economies, including China and India, and methodologically in qualitative and longitudinal analyses (Boiral et al. 2018).

Competitiveness and distributional outcomes of soft instruments

The outcomes for performance or endorsement labels have been associated with positive competitiveness outcomes (*medium evidence, medium agreement*). Out of 19 studies, 89% report positive impact and 11% negligible impact. Although there are several studies analysing competitiveness-related metrics, evidence on most individual metrics is sporadic, except for housing premiums. A large number of studies quantitatively assessing competitiveness find that green labels in buildings are associated with housing price premiums in multiple countries and regions (Fuerst and McAllister 2011; Kahn and Kok 2014; Zhang et al. 2017). Of those studies, 32% were qualitative, associating appliance labelling programmes with employment and industry development (European Commission 2018). There is a research gap in analyses of developing countries, and also in quantitatively assessing outcomes beyond housing price premiums.

A few studies on the distributional outcomes of voluntary labelling programmes point to positive impacts (*limited evidence, high agreement*). All four studies that focus on benefits for consumers and tenants report positive impacts (Devine and Kok 2015). Although there are benefits for utility companies and other stakeholders, more research is needed to specifically attribute these benefits to voluntary labels rather than energy efficiency programmes in general.

Voluntary agreements are associated with positive competitiveness outcomes (*medium evidence, medium agreement*): 14 out of 19 evaluations identified were associated with positive outcomes, while three were associated with negligible outcomes, and two with negative outcomes. Research found an increase in perceived firm financial performance (de Jong et al. 2014; Moon et al. 2014). Studies also show an association with higher exports as more environmentally-conscious trade partners increasingly value environmental certifications (Bellesi et al. 2005). More research is needed to develop evidence on metrics of competitiveness besides firms' financial performance, and especially in developing countries.

Voluntary agreements are associated with a positive impact on distributional outcomes (*limited evidence, high agreement*). Five studies, mainly using qualitative approaches, report a positive association between a firm adopting an environmental management system and impacts on its supply chains. There is a need for more studies with quantitative assessments and geographical diversity.

16.4.4.7 Summary of the Size and Direction of the Evidence of All Policy Instrument Types on Innovation Outcomes

Positive impacts have been identified more frequently in some policies than in others. There is also a lot of variation in the density of the literature. Developing countries are severely underrepresented in the decarbonisation policy instrument evaluation literature aiming to understand the impact on innovation. (*high evidence, high agreement*).

Figure 16.2 below indicates the extent to which some decarbonisation policy instruments have been more or less investigated in terms of their impact on innovation outcomes (as described in Table 16.9). For example, it indicates the extent to which there has been a greater focus of evaluations of the impact of R&D investments, emissions trading schemes and voluntary approaches on innovation. It also shows a limited amount of evidence on procurement, efficiency obligations with tradeable green certificates (TGCs), building codes and auctions.

Figure 16.2 | Number of evaluations available for each policy instrument type covered regarding their impact on innovation and direction of the assessment. The vertical axis displays the number of evaluations claiming to isolate the impact of each policy instrument type on innovation outcomes as listed in Table 16.9. The colour indicates whether each evaluation identified a positive impact on the innovation outcome (blue), the existence of a negative impact (in red), and no impact (in grey). It builds on Grubb et al. (2021), Lilliestam et al. (2021) and Peñasco et al. (2021), and additional studies identified as part of these reviews. TGC stands for tradeable green certificates. TWC stands for tradeable white certificates.

16.4.5 Trade Instruments and their Impact on Innovation

There has been long-standing interest on the impact of Foreign Direct Investment (FDI) on domestic capacity, innovation and environmental outcomes. While this section looks at the impact of trade instruments on innovation, it does not cover the much larger body of evidence on the relationship between FDI and economic development and growth.

Overall, research indicates that trade can facilitate the entrance of new technologies, but the impact on innovation is less clear (*limited evidence, low agreement*). A recent study indicates that, for countries with high environmental performance, FDI has a negligible impact on environmental performance, while countries with a lower environmental performance may benefit from FDI in terms of their environmental performance (Li et al. 2019b). One analysis on China links FDI with improved environmental performance and energy efficiency and also innovation outcomes in general (Gao and Zhang 2013). Other work links FDI with increased productivity across firms (not just those engaged in climate-related technologies) through spillovers (Newman et al. 2015). In addition, Brandão and Ehrl (2019) indicate that productivity of the electric power industry is more influenced by the transfer of embodied technology from other industries than by investments of the power industry. Also, they find that countries with high R&D stocks are the main sources of international technology spillovers and the source countries may also benefit from the spillover.

Other emerging work investigates the role of local content requirements on innovation outcomes and suggests that it can lead to increased power costs (negative distributional impacts). The benefits to the domestic innovation system, measured by patents or exports, are unclear if the policies are not part of a holistic and longer-lasting policy framework (Probst et al. 2020).

16.4.6 Intellectual Property Rights, Legal Framework and the Impact on Innovation

Virtually all countries around the world have instituted systems for the protection of creations and inventions, known as intellectual property rights (IPR) systems (WIPO 2021). While several types of intellectual property exist – patents, copyright, design rights, trademarks, and more – this section will focus on patents, as the most relevant property right for technological innovations (WIPO 2008), and hence the most relevant for policy instruments in this context.

Patent systems aim to promote innovation and economic growth, by stimulating both the creation of new knowledge and diffusion of that knowledge (*high evidence, high agreement*). National patent systems, as institutions, play a central role in theories on national innovation systems (*high evidence, strong agreement*). Patent systems are usually instituted to promote innovation and economic growth (Machlup and Penrose 1950; Nelson and Mazzoleni 1996; Encaoua et al. 2006). Some countries explicitly refer to this purpose in their law or legislation – for instance, the US Constitution states the purpose of the US IP rights system to ‘promote the progress of

science and useful arts’. Patent systems aim to reach their goals by trying to strike a balance between the creation of new knowledge and diffusion of that knowledge (Scotchmer and Green 1990; Devlin 2010; Anadon et al. 2016b). They promote the creation of new knowledge (e.g., technological inventions) by providing a temporary, exclusive right to the holder of the patent, thus providing incentives to develop such new knowledge and helping parties to justify investments in R&D. They promote the diffusion of this new knowledge via the detailed disclosure of the invention in the patent publication, and by enabling a ‘market for knowledge’ via trading patents and issuing licences (Arora et al. 2004). Although IP protections provide incentives to invest in innovation, they can also restrict the use of new knowledge by raising prices or blocking follow-on innovation (Wallerstein et al. 1993; Stiglitz 2008). As institutions, national patent systems feature prominently in models and theories of national innovation systems (Edquist 1997; Klein Woolthuis et al. 2005).

The degree to which patent systems actually promote innovation is subject to debate. Patent protection has been found to have a positive impact on R&D activities in patent-intensive industries, but this effect was found to be conditional on access to finance (Maskus et al. 2019). Patents are believed to be especially important to facilitate innovation in selected areas such as pharmaceuticals, where investments in developments and clinical trials are high, imitation costs are low, and there is often a one-to-one relationship between a patent and a product, referred to as a ‘discrete’ product industry (Cohen et al. 2000). At the same time, an increasing body of theoretical and empirical literature suggests that the proliferation of patents also discourages innovation (*medium evidence, low agreement*). Theoretical contributions note that a appropriability regime that is too stringent may greatly limit the diffusion of advanced technological knowledge and eventually block the development of differentiated technological capabilities within an industry, in what is called an ‘appropriability trap’ (Edquist 1997; Klein Woolthuis et al. 2005). There has been a long-standing debate on the impact of patents and other IP rights on innovation and economic development (Machlup 1958; Hall and Helmers 2019). Jaffe and Lerner (2004) and Bessen and Meurer (2009) highlight how IP rights also hamper innovation in a variety of ways. Other contributions in the literature focus on more specific factors. For example, Shapiro (2001) discusses ‘patent thickets’, where overlapping sets of patent rights mean that those seeking to commercialise new technology need to obtain licences from multiple patentees. Heller and Eisenberg (1998) argue that a ‘tragedy of the anticommons’ is likely to emerge when too many parties obtain the right to exclude others from using fragmented and overlapping pieces of knowledge – ultimately leading to no one having the privilege of using the results of biomedical research. Reitzig et al. (2007) describe the damaging effects of extreme business strategies employing patents, such as ‘patent trolling’.

In general, IP protection and enforcement may have different impacts on economic growth in different types of countries (*limited evidence, high agreement*). There has been a significant degree of harmonisation and cooperation between national IP systems over time. The most recent milestone is the World Trade Organization (WTO) 1994 Trade-Related Aspects of Intellectual Property Rights (TRIPS) Agreement, entered into by all WTO members, which

sets down minimum standards for the regulation by national governments of many forms of IP as applied to nationals of other WTO member nations (WTO 1994). Developing countries successfully managed to include some flexibilities into TRIPS, both in terms of timing of legislative reform, and the content of the reforms. In an attempt to understand the effects of the introduction of TRIPS, Falvey et al. (2006) find that the effect of IP protection on growth is positively and significantly related to growth for low- and high-income countries, but not for middle-income countries. They argue that low-income countries benefit from increased technology flows, but middle-income countries may have offsetting losses from the reduced scope for imitation. Note that Falvey et al. (2006) do not break down their results in different technological areas, and they do not focus on innovation, but instead on growth. It has been argued that the increasingly globalised IP regime through initiatives such as the TRIPS agreement will diminish prospects for technology transfer and competition in developing countries, particularly for several important technology areas related to meeting sustainable development needs (Maskus and Reichman 2017).

In principle, patent holders are not required to take their protected invention into use, and neither have the obligation to allow (i.e., license) others to use the inventions in question (*high evidence, high agreement*). Studies have shown that the way patent holders use their patent differs considerably across industrial sectors: in pharmaceuticals, patents are typically used to enable exclusive production of a certain good (and obtain monopoly rents), while in industries such as computers, semiconductors, and communications, patents are often used to strengthen positions in cross-licensing negotiations and to generate licensing income (Cohen et al. 2000; Foray 2004). There are also companies that predominantly obtain patents for defensive reasons: they seek freedom to design and manufacture, and by owning a patent portfolio themselves, they hope to prevent becoming the target of litigation by other patent holders (Hall and Ziedonis 2001). Patents are often used strategically to impede the development and diffusion of competing, alternative products, processes or services, by employing strategies known as 'blanketing' and 'fencing' (Grandstrand 2000), although the research is not specific to the climate space.

There are notable but specific exceptions to the general principle that patent holders are not obliged to license their patent to others. These exceptions include the compulsory licence, fair, reasonable and non-discriminatory (FRAND) policies, and statement on licences of right (*high evidence, high agreement*). While patent holders are, in principle, free to choose not to license their innovation, there are three important exceptions to this. First, most national patent laws have provisions for compulsory licensing, meaning that a government allows someone else to produce a patented product or process without the consent of the patent holder, or plans to use the patent-protected invention itself (WTO 2020). Compulsory licences may be issued in cases of public interest or events of abuse of the patent (WIPO 2008; Biadgleng 2009). Compulsory licensing is explicitly allowed in the WTO TRIPS agreement, and its use in context of medicine (for instance, to control diseases of public health importance, including HIV, tuberculosis and malaria) is further clarified in the 'DOHA Declaration' from 2001 (Reichman 2009; WHO 2020). Second, standard-setting organisations

have policies to include patented inventions in their standards only if the patent holder is willing to commit FRAND licensing conditions for those patents (Contreras 2015). While a patent holder can choose not to make such a commitment, by doing so, its patent is no longer a candidate for inclusion in the standard. In the (many) fields where standards are of key importance, it is very unusual for patent holders not to be willing to enter into FRAND commitments (Bekkers 2017). Third, when a patent holder files at the patent office and opts for the 'licence of right' regime, in return for reduced patent fees, they enter into a contractual agreement that obliges them to license the patent to those who request it. While not all national patent systems feature this regime, it is a feature present in the new European Community patent (EPO 2017), and may therefore increase in importance.

For a discussion on the impact of intellectual property rights (IPR) on international technology diffusion, see Box 16.9 in Section 16.5.

16.4.7 Sub-national Innovation Policies and Industrial Clusters

Research examining the impacts of sub-national policies on innovation and competitiveness is sporadic – regional variations have been quantitatively assessed in the USA or China, or with case studies in these and other countries. Research on wind energy in the USA, distributed PV balance of systems in China, and renewable energy technologies in Italy have found that policies that incentivised local demand were associated with inducing innovation, measured with patents (Corsatea 2016; Fu et al. 2018; Gao and Rai 2019). Different policies may have different impacts – for example, in the USA, state-level tax incentives and subsidies induced innovation within the state; but for renewable portfolio standards, policies in other states were associated with innovation because of impact on demand, but own-state policies were not (Fu et al. 2018). Research has also noted that the outcomes of policy and regulation on innovation are spatially heterogeneous, because of differences in local planning authorities and capabilities (Corsatea 2016; Song et al. 2019).

Sub-national deployment policies have been associated with different impacts on competitiveness metrics (*limited evidence, medium agreement*). Research on green jobs shows positive association between sub-national policies and green jobs or green firms at the metropolitan level as well as the state or provincial level, in both China and the USA (Yi 2013; Yi and Liu 2015; Lee 2017), while others find no impact of renewable portfolio standards on green job growth in the state (Bowen et al. 2013). Other examples of competitiveness are in the impact of regional green industrial policy in Brazil's Rio Grande do Sul region in attracting auctioned contracts for wind energy (Adami et al. 2017) or in the changes in net positive state revenues associated with removing tax incentives for wind producers in Idaho in the USA (Black et al. 2014).

Sub-national policies also directly support innovation and competitiveness through green incubators and direct grants or R&D funding for local companies working on clean energy, intending to promote local economic development (*limited evidence, medium agreement*). The literature on the impacts of such policies on innovation

and competitiveness is sparse. Some case studies and programme evaluation reports, primarily in the USA, have identified the impacts of sub-national policies on competitiveness — for example, job creation from direct R&D funding in North Carolina (Hall and Link 2015), perceptions for local industry development and support for follow-on financing for companies receiving state-funded grants in Colorado (Surana et al. 2020b), and return on investments for the state in research and innovation spending from the New York state's energy agency (NYSERDA 2020). There is a general paucity of metrics on innovation and competitiveness for systematic assessments of such programmes in developed countries, and even more so in India and other developing countries where such programmes have been increasing (Gonsalves and Rogerson 2019; Surana et al. 2020a).

Although states and local governments increasingly support clean energy deployment as well as directly support innovation, given its link with economic development goals, there is a lack of systematic research on the impacts of these policies at the subnational level. More research – qualitative and quantitative, and in developed and developing countries – is needed to systematically develop evidence on these impacts and to understand the reasons behind regional differences in terms of the type of policy as well as the capabilities in the region.

16.4.8 System-oriented Policies and Instruments

Although previous sections summarised the research disentangling the role of individual policies in advancing or hindering innovation (as well as impacts on other objectives), other research has tried to characterise the impact of a policy mix on a particular outcome. Although the outcome studied was not innovation, but diffusion (technology effectiveness is in the set of criteria outlined in Chapter 13), it seems relevant to discuss overall findings. Research reviewing renewable energy policies in nine OECD countries concludes that, over time, a broad set of policies characterised by a 'balance' metric has been put in place. This research also identifies a significant negative association between the balance of policies in renewable energy and the diffusion of total renewable energy capacity, but no significant effect of the overall intensity (coded as the 46 weighted average of six indicators) on renewable capacity (Schmidt and Sewerin 2019). This indicates that a neutral conception of balance across all possible policies may not be desirable, and that policy mix intensity by itself does not explain technology diffusion.

A growing body of research aims to understand how different policies interact and how to characterise policy mixes (del Rio 2010; Howlett and del Rio 2015; Rogge and Reichardt 2016; del Rio and Cerdá 2017). The empirical impact on the innovation outcomes is not yet discussed. A more detailed discussion of this literature is located in Chapter 13.

An emerging stream of research in complex systems suggests that relatively small changes in policy near a possible tipping point in climate impacts in areas, including changing strategies related to investments in innovation, could trigger large positive societal feedbacks in the long term (Farmer et al. 2019; Otto et al. 2020).

16.5 International Technology Transfer and Cooperation for Transformative Change

This section covers international transfer and cooperation in relation to climate-related technologies, 'the flows of know-how, experience and equipment for mitigating and adapting to climate change amongst different stakeholders' (IPCC 2000) as well as innovation to support transformative change compared to AR5 (IPCC 2014) and the IPCC Special Report on Global Warming of 1.5°C (SR1.5) (IPCC 2018a). This complements the discussion on international cooperation on science and technology in Chapter 14.

This section first outlines the needs and opportunities for international transfer and cooperation on low-emission technologies. It then describes the main objectives and roles of these activities, and then reviews recent institutional approaches within and outside the UN Framework Convention on Climate Change (UNFCCC) to support international technology transfer and cooperation. Finally, it discusses emerging ideas for international technology transfer and cooperation, and possible modifications to support the achievement of climate change and Sustainable Development Goals (SDGs), building up to Section 16.6.

16.5.1 International Cooperation on Technology Development and Transfer: Needs and Opportunities

With the submission of their Nationally Determined Contributions (NDCs) as part of the Paris Agreement, most developing countries are now engaged in climate mitigation and adaptation. While technology is seen as one of the 'means of implementation' of climate action, developing countries often have relatively limited technology innovation capabilities, which requires them to access technologies developed in higher-income countries with stronger innovation systems (Popp 2011; Binz et al. 2012; Urban 2018). In many cases, these technologies require adaptation for the local context and needs (Sagar 2009; Anadon et al. 2016b), and innovation capabilities are required to suitably adapt these technologies for local use and also to create new markets and business models that are required for successful deployment (Sagar 2009; Ockwell et al. 2015; Ockwell and Byrne 2016). This can lead to dependencies on foreign knowledge and providers (Ockwell and Byrne 2016), negative impacts in terms of higher costs (Huenteler et al. 2016a), balance of payments constraints, and vulnerability to external shocks (Ebeling 2020).

The climate technology transition can also yield other development benefits, for instance better health, increased energy access, poverty alleviation and economic competitiveness (Deng et al. 2018), including industrial development, job creation and economic growth (Porter and Van der Linde 1995; Altenburg and Rodrik 2017; Lema et al. 2020; Pegels and Altenburg 2020) (Section 16.6). The growing complexity of technologies and global competition have made technology development a globalised process involving the flow of knowledge and products across borders (Lehoux et al. 2014; Koengkan et al. 2020). For instance, in electronics production, Asian economies have captured co-location synergies and dominate

production and assembly of product components, whereas American firms have adopted 'design-only' strategies (Tassey 2014). In the context of renewable energy technologies, 'green global division of labour' has been observed, with countries specialising in investments in research and development (R&D), manufacturing or deployment of renewables (Lachapelle et al. 2017). In the case of solar photovoltaic (PV), for example, while many technical innovations emerged from the USA, Japan and China emphasised the manufacture of physical modules (Deutch and Steinfeld 2013) (Box 16.4).

Such globalisation of production and supply chains opens up economic development opportunities for developing countries (Lema et al. 2020). At the same time, not all countries benefit from the globalisation of innovation – barriers remain related to finance, environmental performance, human capabilities and cost (Weiss and Bonvillian 2013; Egli et al. 2018), with developing countries being particularly disadvantaged at leveraging these opportunities. The gap in low-carbon technology innovation between countries appears to have reduced only among OECD countries (Yan et al. 2017; Du and Li 2019; Du et al. 2019) and the lower-income countries are not able to benefit as much from low-carbon technologies. For instance, in the case of agriculture, Fuglie (2018) notes that international R&D spillovers seem to have benefitted developed countries more than developing countries. Gross et al. (2018) also argue that the development timescales for new energy technologies can extend up to 70 years, even within one country. They recommend that innovation efforts be balanced between early-stage R&D spending, and commercialising already low-emission technologies in the demonstration phase and diffusing them globally.

Thus international cooperation on technology development and transfer can enable developing countries to achieve their climate goals more effectively, while also addressing other SDGs – taking advantage, where possible, of the globalisation of innovation and production (Lema et al. 2020). Earlier assessments in AR5 and SR1.5 have made it clear that international technology transfer and cooperation could play a role in climate policy at both the international and the domestic policy level (Somanathan et al. 2014; Stavins et al. 2014; IPCC 2018b) and for low-carbon development at the regional level (Agrawala et al. 2014). The Paris Agreement also reflects this view by noting that countries shall strengthen cooperative action on technology development and transfer regarding two main aspects: (i) promoting collaborative approaches to R&D; and (ii) facilitating access to technology to developing country Parties (UNFCCC 2015). Furthermore, both in literature and in UNFCCC deliberations, South-South technology transfer is highlighted (Khosla et al. 2017) as a complement to the transfer of technology and know-how from the North to the South.

This is consistent with literature that suggests that greenhouse gas (GHG) mitigation in developing countries can be enhanced by: (i) technology development and transfer collaboration and a 'needs-driven' approach; (ii) development of the specific types of capacity required across the entire innovation chain; and (iii) strengthening of the coordination and agendas across and between governance levels (including domestic and international levels) (Khosla et al. 2017; Zhou 2019; Upadhyaya et al. 2020).

16.5.2 Objectives and Roles of International Technology Transfer and Cooperation Efforts

International efforts involving technology transfer can have different objectives and roles. These include access to knowledge and financial resources as well as promotion of new industries in both the developed and recipient country (Huh and Kim 2018). Based on an econometric analysis of international technology transfer factors and characteristics of Clean Development Mechanism (CDM) projects, Gandenberger et al. (2016) find that complexity and novelty of technologies explain whether a CDM project includes hardware technology transfer, and that factors like project size and absorptive capacity of the host country do not seem to be drivers. Halleck Vega and Mandel (2018) argue that 'long-term economic relations', for instance being part of a customs union, affect technological diffusion between countries in the case of wind energy, and indicate that this has resulted in low-income countries being largely overlooked.

There is some literature studying whether technology cooperation could complement or replace international cooperation based on emission reductions, such as in the Kyoto Protocol, and whether that would have positive impacts on climate change mitigation and compliance. A handful of papers conducted game-theoretic analysis on technology cooperation, sometimes as an alternative for cooperation on emission reductions, and found partially positive effects (Bosetti et al. 2017; Narita and Wagner 2017; Rubio 2017; Verdolini and Bosetti 2017). However, Sarr and Swanson (2017) model that, due to the rebound effect, technology development and transfer of resource-saving technologies may not lead to envisioned emission reductions.

While technology cooperation can be aimed at emission reduction through mitigation projects, as indicated above, not all cooperative actions directly result in mitigation outcomes. Overall, technology transfer broadly has focused on: (i) enhanced climate technology absorption and deployment in developing countries; and (ii) enhanced research, development and demonstration (RD&D) through cooperation and knowledge spillovers.

16.5.2.1 Enhancing Low-emission Technology Uptake in Developing Countries

Real-world outcomes in terms of low-emission technology deployment in developing countries may vary significantly, depending on the nature of the international engagement and the domestic context. While there has been some success in the enhancement of technology deployment through technology transfer in some developing countries (de la Tour et al. 2011; Zhang and Gallagher 2016), many others, and particularly least-developed countries, are lagging behind (Glachant and Dechezleprêtre 2017). Glachant and Dechezleprêtre (2017) indicate that this is due to the lack of participation in economic globalisation and that climate negotiations could facilitate technology transfer to those countries through the creation of global demand for low-emission technologies through stronger mitigation targets that will result in lowering of costs and therefore enhanced technology diffusion. A broader perspective presents a host of other factors that govern technology diffusion and commercialisation in developing countries, including: investment;

social, cultural and behavioural, marketing and market building; macroeconomics; and support policy (Bakhtiar et al. 2020). Ramos Mejia et al. (2018) indicate that the governance of low-emission technology transfer and deployment in developing countries is frequently negatively affected by a mixture of well- and ill-functioning institutions – for instance, in a context of market imperfection, clientelist and social exclusive communities and patrimonial and/or marketised states. Furthermore, existing interests, such as fossil fuel production, may also impede the deployment of low-emission technologies, as highlighted in case studies of Vietnam and Indonesia (Dorband et al. 2020; Ordonez et al. 2021). It is for such reasons that both domestic efforts and international engagement are seen as necessary to facilitate technology transfer as well as deployment in developing countries (Boyd 2012). The same has been seen as true in the case of agriculture, where the very successful international research efforts of the CGIAR – with remarkably favourable benefit-cost ratios (Alston et al. 2021) – were complemented by the national agricultural research systems for effective uptake of high-yielding varieties of crops (Evenson and Gollin 2003).

One key area for underpinning effective technology uptake in developing countries relates to capabilities for managing technological change. This includes the capabilities to innovate, implement, and undertake integrated planning. There is much research to indicate that the ability of a country's firms to adopt new technologies is determined by its absorptive capacity, which includes its own R&D activities, human capacity (e.g., technical personnel), government involvement (including institutional capacity), the infrastructure in the country (Kumar et al. 1999), and knowledge and capacity as part of its 'intangible assets' or the 'software' (Ockwell et al. 2015; da Silva et al. 2019; Corsi et al. 2020). For sustainable development, the capacity to plan in an integrated way and implement the SDGs (Khalili et al. 2015; Elder et al. 2016), including using participatory approaches (Disterheft et al. 2015), is a conditional means of implementation. It also is argued that, if human capital were the focus of international climate negotiations as well as national climate policy, it could change the political economy in favour of climate mitigation, which is needed for developing such capabilities in advance to keep up with the required speed of transformation (Ockwell et al. 2015; Hsu 2017; IPCC 2018b; Upadhyaya et al. 2020). In a global analysis of wind energy using econometric analysis, Halleck-Vega et al. (2018) lend quantitative credibility to the claim that a technology skill base is a key determinant of technological diffusion. Activities to enhance capabilities include informational contacts, research activities, consulting, education and training, and activities related to technical facilities (Huh and Kim 2018; Khan et al. 2020).

There are multiple studies drawing on empirical work that also support this conclusion. For South-South technology transfer between India and Kenya, not just technical characteristics, but also mutual learning on how to address common problems of electricity access and poverty, was suggested as an important condition for success (Ulsrud et al. 2018). Olawuyi (2018) discusses the specific capability gap in Africa, despite decades of technology transfer efforts under various mechanisms and programmes of the UNFCCC. The study suggests that barriers need to be resolved by African countries themselves, in particular: inadequate access to information about

imported climate technologies; lack of domestic capacities to deploy and maintain imported technologies; the weak regulatory environment to stimulate clean technology entrepreneurship; the absence or inadequacy of climate change laws; and weak legal protection for imported technologies. Moreover, Ziervogel et al. (2021) indicate that, for transformative adaptation, transdisciplinary approaches and capacity-building shifting, 'the co-creation of contextual understandings' instead of top-down transfer of existing knowledge would deliver better results. Despite the understanding of the importance of the capacity issue, significant gaps still remain on this front (TEC 2019) (Section 16.5.4).

16.5.2.2 Enhancing RD&D and Knowledge Spillovers

As mentioned earlier, RD&D can aid the development of new technologies as well as their adoption for new use contexts. Therefore, it is not surprising that international cooperation on RD&D is identified as a mechanism to promote low-carbon innovation (Suzuki 2015; Mission Innovation 2019; TEC 2021). This has resulted in a variety of international initiatives to cooperate on technology in order to create knowledge spillovers and develop capacity. For example, the UNFCCC Technology Mechanism, among other things, aims to facilitate finance for RD&D of climate technologies by helping with readiness activities for developing country actors. In particular preparing early-stage technologies for a smoother transition to deployment and commercialisation has been emphasised in the context of the Technology Executive Committee (TEC) (TEC 2017). There are numerous multilateral, bilateral and private programmes that have facilitated RD&D, biased mostly towards mitigation (as opposed to adaptation) activities. Many programmes that seemed to be about RD&D were in reality dialogues about research coordination (Ockwell et al. 2015). There are also a variety of possible bilateral and multilateral models and approaches for engaging in joint R&D (Mission Innovation 2019). An update by the TEC (2021) reviewing good practices in international cooperation of technology confirmed the conclusions of Ockwell et al. (2015), and moreover highlighted that most initiatives are led by the public sector, and that the private sector tended to get involved only in incubation, commercialisation and diffusion phases. It also concluded that, although participation of larger, higher-income developing countries seems to have increased, participation of least-developed countries is still very low.

16.5.3 International Technology Transfer and Cooperation: Recent Institutional Approaches

The sections below discuss the literature on various categories of international technology cooperation and transfer.

16.5.3.1 UNFCCC Technology and Capacity-building Institutions

Technology development and transfer have been a part of UNFCCC discussions and developments in the context of the international climate negotiations ever since its agreement in 1992, as assessed in AR5 (Stavins et al. 2014). Support on 'Technology Needs Assessment' to developing countries was the first major action undertaken by the UNFCCC, and this has undergone different cycles of learning

Box 16.8 | Capacity Building and Innovation for Early Warning Systems in Small Island Developing States

One of the areas of international cooperation on capacity building is adaptation, which has been highlighted by both the Technology Executive Committee (TEC) (Ockwell et al. 2015; TEC 2015) and the Paris Committee on Capacity-building (UNFCCC 2020b) as an area where capacity gaps remain, especially in Small Island Developing States (SIDS).

While adaptation was initially conceived primarily in terms of infrastructural adjustments to long-term changes in average conditions (e.g., rising sea levels), a key innovation in recent years has been to couple such long-term risk management to existing efforts to manage disaster risk, specifically including early warning systems, enabling early action in the face of climate- and weather-risk at much shorter timescales (IPCC 2012), with potentially significant rates of return (Rogers and Tsirkunov 2010; Hallegatte 2012; Global Commission on Adaptation 2019).

In recent years, deliberate international climate finance investments have focused on ensuring that developing countries (and especially SIDS and least-developed countries) have access to improvements in hydrometeorological observations, modelling, and prediction capacity, sometimes with a particular focus on the people intended to benefit from the information produced (CREWS 2016). For instance, on the Eastern Caribbean SIDS of Dominica, researchers took a community-based approach to identify the mediating factors affecting the challenges to coastal fishing communities in the aftermath of two extreme weather events (in particular hurricane Maria in 2017) (Turner et al. 2020). Adopting an adaptive capacity framework (Cinner et al. 2018), they identified 'intangible resources' that people relied on in their post-disaster response as important for starting up fishery, but also went beyond that framework to conclude that the response ability on the part of governmental organisations as well as other actors (e.g., fish vendors) in the supply chain is also a requirement for rebuilding and restarting income-generating activity (Turner et al. 2020). Numerous other studies have highlighted capacity-building as adaptation priorities (Basel et al. 2020; Kuhl et al. 2020; Sarker et al. 2020; Vogel et al. 2020; Williams et al. 2020).

One of several helpful innovations in these efforts is impact-based forecasting (Harrowsmith et al. 2020), which provides forecasts targeted at the impact of the hazard rather than simply the meteorological variable. This enables a much easier coupling to early action in response to the information, and a more appropriate response afterwards. Automatic responses to warnings have also been adopted in the humanitarian field for anticipatory action ahead of (rather than simply in response to) disasters triggered by natural hazards (Coughlan de Perez et al. 2015). This has resulted in a rapid scale-up of such anticipatory financing mechanisms to tens of countries over the past few years, and emerging evidence of its effectiveness. Still, the response is lacking in coherence and comprehensiveness, resulting in calls for a more systematic evidence agenda for anticipatory action (Weingartner et al. 2020).

(Nygaard and Hansen 2015; Hofman and van der Gaast 2019). Since 2009, the UNFCCC discussions on technology development and transfer have focused on the Technology Mechanism under the Cancun Agreements of 2010, which can be seen as the global climate governance answer to redistributive claims by developing countries (McGee and Wenta 2014). The Technology Mechanism consists of the TEC and the Climate Technology Centre & Network (CTCN). An independent review of CTCN, evaluated it on five dimensions – relevance, effectiveness, efficiency, impacts and sustainability – and indicated that the organisation is achieving its mandate in all these dimensions, although there are some possible areas of improvement. The review also specifically noted that 'the lack of predictability and security over financial resources significantly affected the CTCN's ability to deliver services at the expected level, as did the CTCN's lack of human and organizational resources and the capacity of NDEs [National Designated Entities].' (TEC 2017). The CTCN has overcome some of the limitations imposed by resource constraints by acting as a matchmaker from an open-innovation perspective (Lee and Mwebaza 2020). The CTCN's lack of financial sustainability has been a recurring issue, which may potentially be resolved by deepening the linkage between the CTCN and Green Climate Fund (Oh 2020). In the meanwhile, the Green Climate Fund is planning to

establish the Climate Innovation Facility to support and accelerate early-stage innovations and climate technologies through the establishment of regional innovation hubs and climate accelerators as well as a climate growth fund (Green Climate Fund 2020).

The 'technology' discussion has been further strengthened by the Paris Agreement, in which Article 10 is fully devoted to technology development and transfer (UNFCCC 2015). However, the political discussions around technology continue to be characterised by viewing technology mostly as hardware (Haselip et al. 2015), and relatively limited in scope (de Coninck and Sagar 2017). The workplans of the TEC and the CTCN do, however, indicate a broadening of the perspective on technology (CTCN 2019; TEC 2019).

Since the Kyoto Protocol's CDM has been operational, studies have assessed its hypothesised contribution to technology transfer, including transfer of knowledge. Though not an explicit objective of the CDM, numerous papers have investigated whether CDM projects contribute to technology transfer (Michaelowa et al. 2019). The literature varies in its assessment. Some find extensive use of domestic technology and hence lower levels of international technology transfer (Doranova et al. 2010), while others indicate

that around 40% of projects feature hardware or other types of international transfer of technology (Seres et al. 2009; Murphy et al. 2015), depending on the nature of technology, the host country and region (Cui et al. 2020) and the project type (Karakosta et al. 2012). The CDM was generally positively evaluated on its contribution to technology transfer. However, it was also regarded critically as the market-responsiveness and following of export implies a bias to larger, more advanced economies rather than those countries most in need of technology transfer (Gandenberger et al. 2016), although some countries have managed to correct that by directing the projects, sub-nationally, to provinces with the greatest need (Bayer et al. 2016). Also, the focus on hardware in evaluations of technology transfer under the CDM has been criticised (Haselip et al. 2015; Michaelowa et al. 2019). Indeed, although many studies do go beyond hardware in their evaluations (e.g., Murphy et al. 2015), the degree to which the project leads to a change in the national system of innovation or institutional capacity development is not commonly assessed, or has been assessed as limited (de Coninck and Puig 2015).

There is significantly less literature on capacity building under the UNFCCC, especially as it relates to managing the technology transition. In a legal analysis, D'Auvergne and Nummelin (2017) indicate the nature, scope and principles of Article 11 on capacity building of the Paris Agreement as being demand- and country-driven, following a needs approach, fostering national, subnational and local ownership, and being iterative, incorporating the lessons learnt, as well as participatory, cross-cutting and gender-response. They also highlight that it is novel that least-developed countries and Small Island Developing States (SIDS) are called out as the most vulnerable and most in need of capacity building, and that it raises a 'legal expectation' that all parties 'should' cooperate to enhance the capacity in developing countries to implement the Paris Agreement. These aspects are reflected in the terms of reference of the Paris Committee on Capacity-building (PCCB) that was established in 2015 at the 21st Conference of the Parties (UNFCCC 2016; D'Auvergne and Nummelin 2017), and was extended by five years at the 25th Conference of the Parties in 2019 (UNFCCC 2020a, b). In its work plan for 2020–2024, its aims include 'identifying capacity gaps and needs, both current and emerging, and recommending ways to address them'.

An example of how innovative technologies combined with capacity development, and how institutional innovation is combined in the context of adaptation to extreme weather in SIDS can be found in Box 16.8.

From the broader assessment above, despite limitations of available information, it is clear that the number of initiatives and activities on international cooperation and technology transfer and capacity building seem to have been enhanced since the Cancun Agreements and the Paris Agreement (TEC 2021). However, much more can be done, given the complexity and magnitude of the requirements in terms of coverage of activities, the amount of committed funding, and its effectiveness. Some assessments of UNFCCC instruments specifically for technology transfer to developing countries have indicated that functions such as knowledge development, market formation and legitimacy in developing countries' low-emission technological innovation systems would need much more support to fulfil the Paris Agreement goals (de Coninck and Puig 2015; Ockwell et al. 2015); such areas would benefit from continued attention, given their role in the overall climate technology transition.

16.5.3.2 International RD&D Cooperation and Capacity-building Initiatives

Besides the UNFCCC mechanisms, there are numerous other initiatives that promote international cooperation on RD&D as well as capacity building. Some of them are based on the notion of 'mission-oriented innovation policy' (Mazzucato and Semieniuk 2017; Mazzucato 2018), which shapes markets rather than merely corrects market failures.

For instance, Mission Innovation is a global initiative consisting of 23 member countries and the European Commission working together to reinvigorate and accelerate global clean energy innovation with the objective to make clean energy widely affordable with improved reliability and secured supply of energy. The goal is to accelerate clean energy innovation in order to limit the rise in the global temperature to well below 2°C. The members seek to foster international collaboration among its members and increase public investments in clean energy R&D with the engagement of the private sector. A recent assessment shows that, although

Box 16.9 | Intellectual Property Rights (IPR) Regimes and Technology Transfer

In the global context of climate mitigation technologies, it has been noted that technologies have been developed primarily in industrialised countries but are urgently required in fast-growing emerging economies (Dechezleprêtre et al. 2011). International technology transfers can take place via three primary channels: (i) trade in goods, where technology is embedded in products; (ii) Foreign Direct Investment (FDI), where enterprises transfer firm-specific technology to foreign affiliates; and (iii) patent licences, where third parties obtain the right to use technologies. IPRs are relevant for all these three channels.

Not surprisingly, the role of IPRs in international transfer of climate mitigation technologies has been much discussed but also described as particularly controversial (Abdel-Latif 2015). The relationships between IPR, innovation, international technology transfer and local mitigation and adaptation are complex (Maskus 2010; Abdel-Latif 2015; Li et al. 2020) and there is no clear consensus on what kind of an IPR regime will be most beneficial for promoting technology transfer.

Box 16.9 (continued)

Several studies argue that, particularly in developing nations, the global IPR regime has resulted in delayed access, reduced competition and higher prices (Littleton 2008; Zhuang 2017) and that climate-change-related technology transfer is insufficiently stimulated under the current IPR regime. Compulsory licensing (as already used in medicine) is one of the routes proposed to repair this (Littleton 2008; Abdel-Latif 2015).

There is little systematic evidence that patents and other IPRs restrict access to environmentally-sound technologies, since these technologies are mostly in sectors based on mature technologies where numerous substitutes among global competitors are available (Maskus 2010). This might, however, change in the future – for instance, with new technologies based on plants, via biotechnologies and synthetic fuels (Maskus 2010), for which Correa et al. (2020) already find some evidence.

There is also literature suggesting that weak IPR regimes have a ‘strong and negative impact on the international diffusion of patented knowledge’ (Dechezleprêtre et al. 2013; Glachant and Dechezleprêtre 2017). Also, patents may support market transactions in technology, including international technology transfer, especially to middle-income countries and larger developing countries (Maskus 2010; Hall and Helmers 2019) but least-developed countries may be better served by building capacity to absorb and implement technology (Hall and Helmers 2010; Maskus 2010; Sanni et al. 2016; Glachant and Dechezleprêtre 2017). It is also argued that it is not even clear that the patent system as it exists today is the most appropriate vehicle for encouraging international access (Hall and Helmers 2010; Maskus 2010; Sanni et al. 2016; Glachant and Dechezleprêtre 2017). Given the large variation in perspectives on the role of IPRs in technology transfer, there is a need for more evidence and analysis to better understand if, and under what conditions, IPR may hinder or promote technology transfer (TEC 2012).

In terms of ways forward to meet the challenge of climate change, different suggestions are made in the context of IPR that can help to further improve international technology transfer of climate mitigation technologies, including through the Trade-Related Aspects of Intellectual Property Rights (TRIPS) Agreement, by making decisions on IPR to developing countries on a case-by-case basis, by developing countries experimenting more with policies on IPR protection, or through brokering or patent-pooling institutions (Littleton 2009; Maskus and Reichman 2017; Dussaux et al. 2018). Others also suggest that distinctions among country groups be made on the basis of levels of technological and economic development, with least-developed countries getting particular attention (Zhuang 2017; Abbott 2018).

expenditures are rising, the aims were not met by 2020 (Myslikova and Gallagher 2020). Gross et al. (2018) caution against too much focus on R&D efforts for energy technologies to address climate change, including for Mission Innovation. They argue that, given the timescales of commercialisation, developing new technologies now would mean they would be commercially too late for addressing climate change. Huh and Kim (2018) discuss two ‘knowledge and technology transfer’ projects that were eventually not pursued beyond the feasibility study phase due to cooperation and commitment problems between national and local governments, and they highlight the need for ownership and engagement of local residents and recipient governments.

Intellectual property rights (IPR) regimes (Box 16.9) can be an enabler or a barrier to energy transition. For more background on IPR and impact on innovation, see Section 16.4.6.

16.5.4 Emerging Ideas for International Technology Transfer and Cooperation

As with the broader innovation literature (Section 16.3), and drawing on such literature, there has been an emergence of a greater understanding of, and emphasis on, the role of innovation systems (at national, sectoral, and technological levels) as a way to help

developing countries with the climate technology transition (TEC 2015; Ockwell and Byrne 2016). This has given rise to several proposals, discussed here and summarised in Figure 16.3.

Enhancing deployment and diffusion of climate technologies in developing countries would require a variety of actors with sufficient capabilities (*robust evidence, medium agreement*) (Kumar et al. 1999; Sagar et al. 2009; Ockwell et al. 2018). This may include strengthening existing actors (Malhotra et al. 2021), supporting science, technology, and innovation-based start-ups to meet social goals (Surana et al. 2020b), and developing entities and programmes that are intended to address specific gaps relating to technology development and deployment (Sagar et al. 2009; Ockwell et al. 2018).

There is also an increasing emphasis on the relevance of participative social innovation, local grounding and policy learning as a replacement of the expert-led technological change (Chaudhary et al. 2012; Disterheft et al. 2015; Kowarsch et al. 2016). Others have suggested a shift to international innovation cooperation rather than technology transfer, which implies a donor-recipient relationship. The notion of innovation cooperation also makes more explicit the focus on innovation processes and systems (Pandey et al. 2021). A broad transformative agenda therefore proposes that contemporary societal challenges are complex and multivariiegated in scope and will require the actions of a diverse set of actors to formulate and address the

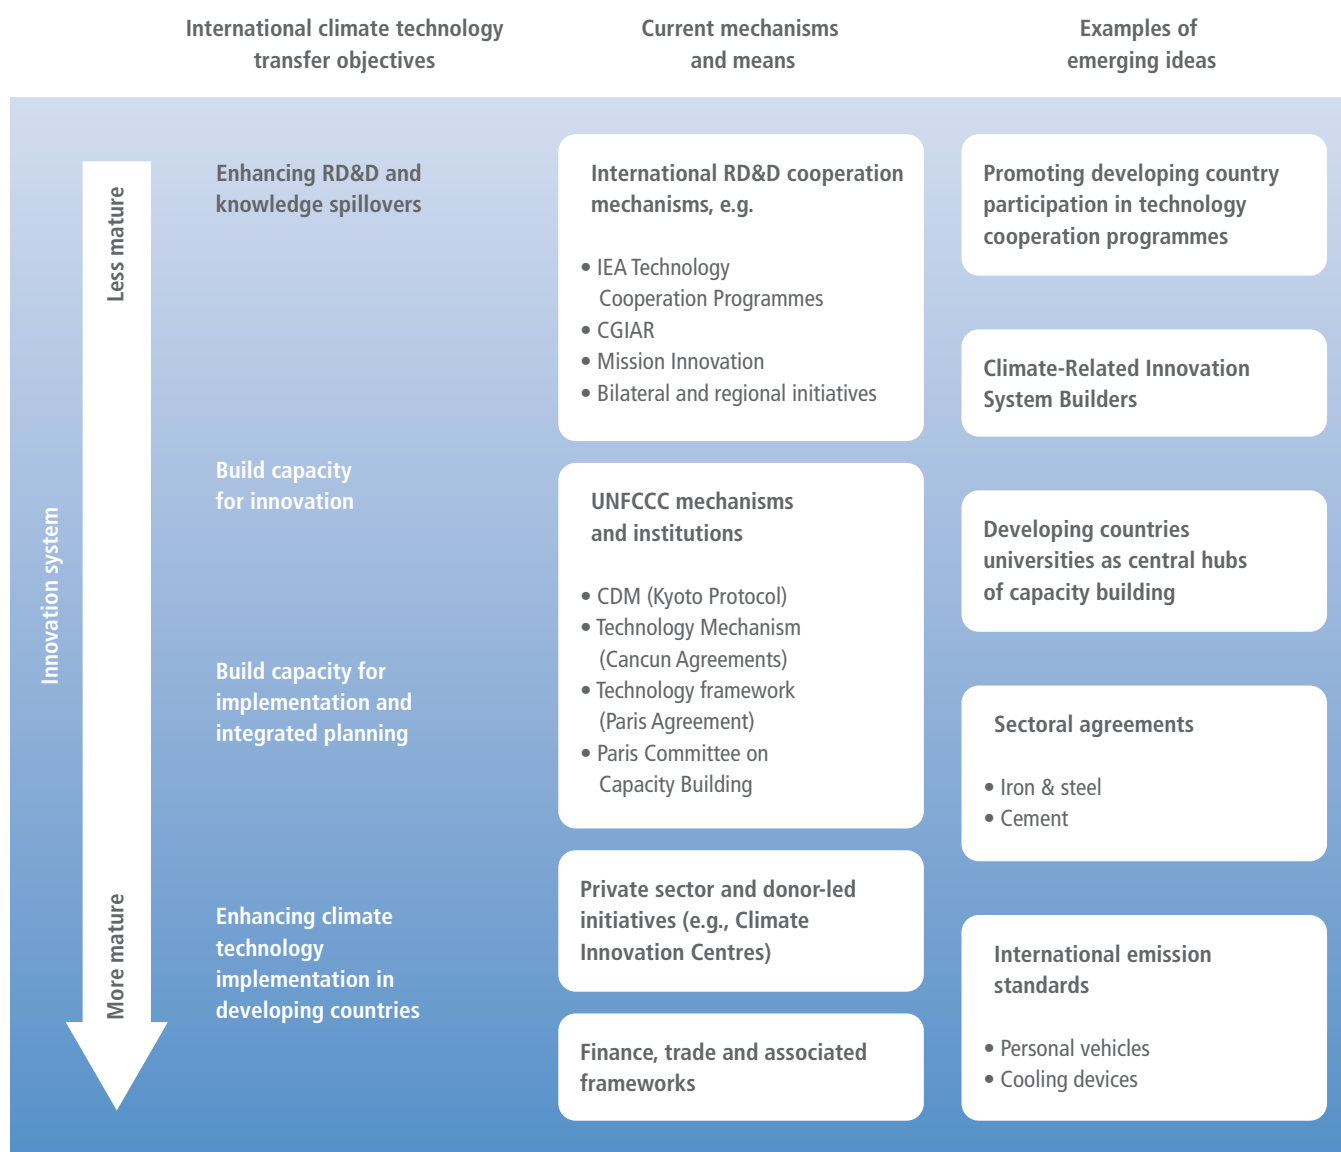

Figure 16.3 | Examples of recent mechanisms and emerging ideas (right column) in relation to level of maturity of the national or technological innovation system, objectives of international climate technology transfer efforts and current mechanisms and means. Sources: Sagar (2009); Ockwell and Byrne (2016); Khan et al. (2020); Oberthür et al. (2021).

policy, implying that social, institutional and behavioural changes next to technological innovations are the possible solutions (Geels 2004) (see also Cross-Chapter Box 12 in this chapter).

Several authors have proposed new mechanisms for international cooperation on technology. Ockwell and Byrne (2016) argue that a role for the UNFCCC Technology Mechanism could be to support Climate Relevant Innovation-system Builders (CRIBs) in developing countries, institutions locally that develop capabilities that ‘form the bedrock of transformative, climate-compatible, technological change and development’. Khan et al. (2020) propose a specific variant with universities in developing countries serving as ‘central hubs’ for capacity building to implement the NDCs as well as other climate policy and planning instruments; they also suggest that developing countries outline their capacity-building needs more clearly in their NDCs.

Building on an earlier discussion of technology-oriented and sectoral agreements (Meckling and Chung 2009) and the potential for international cooperation in energy-intensive industry (Åhman et al. 2017), where deep emission reduction measures require transformative changes (Chapter 11), Oberthür et al. (2021) propose that a way forward for the global governance for energy-intensive industry could be through sub-sector ‘clubs’ that include governmental, private and societal actors (Oberthür et al. 2021).

Figure 16.3 summarises examples of emerging ideas for international cooperation on climate technology, their relation to the objectives and existing efforts, and the level of development of the innovation system around a technology (Hekkert et al. 2007; Bergek et al. 2008) or in nations (Lundvall et al. 2009).

16.6 Technological Change and Sustainable Development

This section considers technological innovation in the broader context of sustainable development, recognising that technological change happens within social and economic systems, and therefore technologies are conceived and applied in relation to those systems (Grübler 1998). Simplifications of complex interactions between physical and social systems and incomplete knowledge of the indirect effects of technological innovation may systematically lead to underestimation of environmental impacts and overestimation of our ability to mitigate climate change (Hertwich and Peters 2009; Arvesen et al. 2011).

Previous sections of the chapter discussed how a systemic approach, appropriate public policies and international cooperation on innovation can enhance technological innovation. This section provides more details on how innovation and technological change, sustainable development and climate change mitigation intertwine.

16.6.1 Linking Sustainable Development and Technological Change

Sustainable development and technological change are deeply related (UNCTAD 2019). Technology has been critical for increasing productivity as the dominant driving force for economic growth.

Also, the concentration of technology in few hands has boosted consumption of goods and services which are not necessarily aligned with the Sustainable Development Goals (SDGs) (Walsh et al. 2020). It has been suggested that, in order to address sustainable development challenges, science and technology actors would have to change their relation to policymakers (Ravetz and Funtowicz 1999) as well as the public (Jasanoff 2003). This has been further elaborated for the SDGs. The scale and ambition of the SDGs call for a change in development patterns that require a fundamental shift in: current best practices; guidelines for technological and investment decisions; and the wider socio-institutional systems (UNCTAD 2019; Pegels and Altenburg 2020). This is needed as not all innovation will lead to sustainable development patterns (Altenburg and Pegels 2012; Lema et al. 2015).

Current SDG implementation gaps reflect, to some extent, inadequate understanding of the complex relationships among the goals (Waiswa et al. 2019; Skene 2020), as well as their synergies and trade-offs, including how they limit the range of responses available to communities and governments, and potential injustices (Thornton and Comberti 2017). These relationships have been approached by focusing primarily on synergies and trade-offs while lacking the holistic perspective necessary to achieve all the goals (Nilsson et al. 2016; Roy et al. 2018).

A more holistic framework could envisage the SDGs as outcomes of stakeholder engagement and learning processes directed at achieving a balance between human development and environmental protection

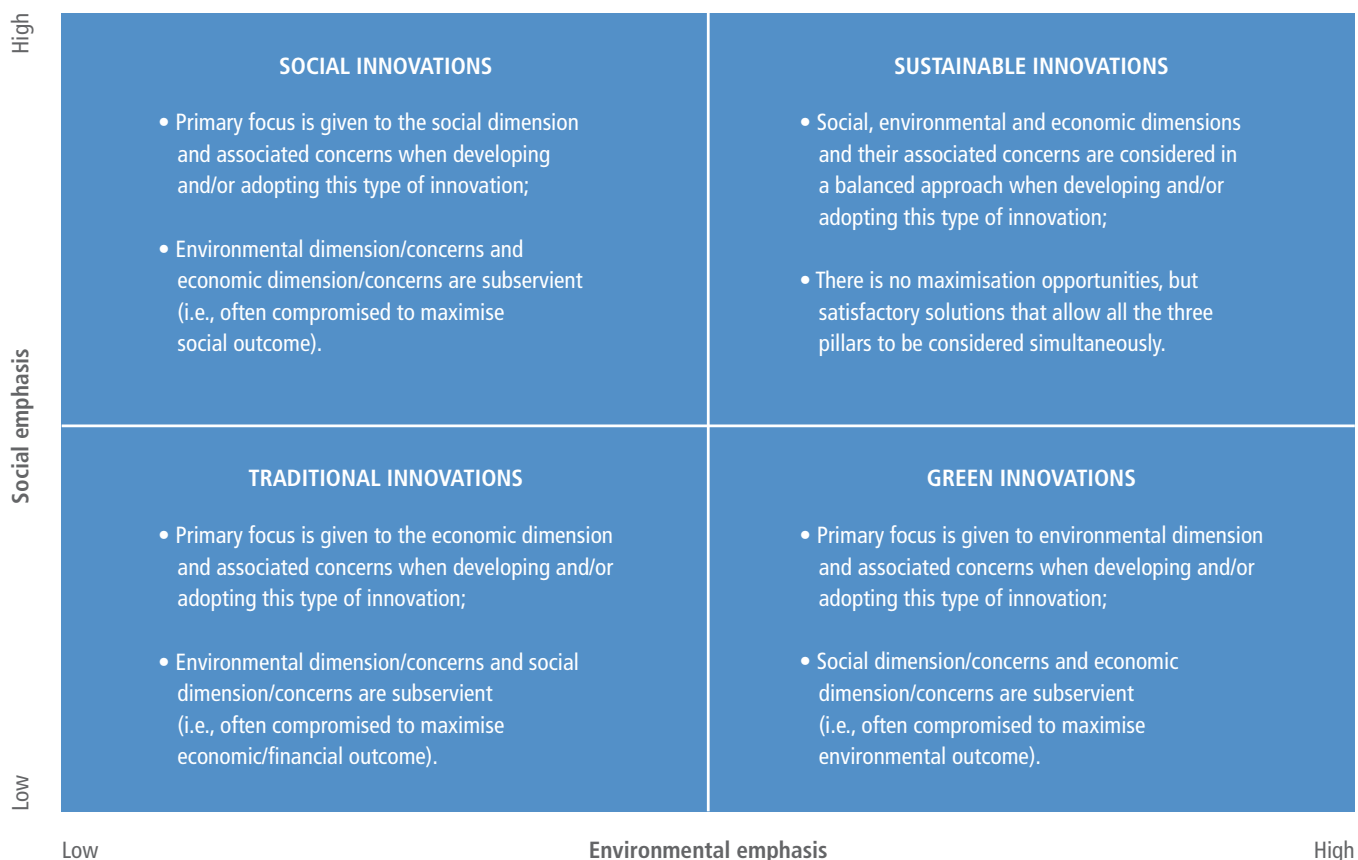

Figure 16.4 | Considerations and typology of innovations for sustainable development. Source: Silvestre and Țîrcă (2019).

(Gibbons 1999; Jasanoff 2003), to the extent that the two can be separated. From a science, technology and innovation perspective, Fu et al. (2019) distinguish three categories of SDGs. The first category comprises those SDGs representing essential human needs for which inputs that put pressure on sustainable development would need to be minimised. These include Zero hunger (SDG 2), Clean water and sanitation (SDG 6) and Affordable and clean energy (SDG 7) resources, which continue to rely on production technologies and practices that are eroding ecosystem services, potentially hampering the realisation of SDGs 15 (Life on land) and 14 (Life below water) (Díaz et al. 2019). The second category includes those related to governance and which compete with each other for scarce resources, such as Industry, innovation and infrastructure (SDG 9) and Climate action (SDG 13), which require an interdisciplinary perspective. The third category are those that require maximum realisation, include No poverty (SDG 1), Quality education (SDG 4) and Gender equality (SDG 5) (Fu et al. 2019).

Resolving tensions between the SDGs requires adoption and mainstreaming of novel technologies that can meet needs while reducing resource waste and improving resource-use efficiency, and acknowledging the systemic nature of technological innovation, which involves many levels of actors, stages of innovation and scales (Anadon et al. 2016b). Changes in production technology have been found effective to overcome trade-offs between food and water goals (Gao and Bryan 2017). Innovative technologies at the food, water and energy nexus are transforming production processes in industrialised and developing countries, such as developments in agrivoltaics, which is co-development of land for agriculture and solar with water conservation benefits (Barron-Gafford et al. 2019; Lytle et al. 2020; Schindele et al. 2020), and other renewably powered low- to zero-carbon food, water and energy systems (He et al. 2019). Silvestre and Țircă (2019) indicate that maximising both social and

environmental aims is not possible, but that sustainable innovations include satisfactory solutions for social, environmental and economic pillars (Figure 16.4).

There is evidence that technological changes can catalyse implementation of the reforms needed to the manner in which goods and services are distributed among people (Fu et al. 2019). A recently developed theoretical framework based on a capability approach (CA) has been used to evaluate the quality of human life and the process of development (Haenssger and Ariana 2018). Variations of the CA have been applied to exploratory studies of the link between technological change, human development, and economic growth (Mayer 2001; Mormina 2019). This suggests that the transformative potential of technology as an enabling condition is not intrinsic, but is assigned to it by people within a given technological context. A failure to recognise and account for this property of technology is a root cause of many failed attempts at techno-fixing sustainable development projects (Stilgoe et al. 2013; Fazey et al. 2020).

The basic rationale for governance of technological change is the creation and maintenance of an enabling environment for climate and SDG-oriented technological change (Avelino et al. 2019). Such an environment poses high demands on governance and policy to coordinate with actors and provide a direction for innovation and technological change. Cross-Chapter Box 12 illustrates how the dynamics of socio-technical transitions and shifting development pathways towards sustainable development offer options for policymakers and other actors to accelerate the system transitions needed for both climate change mitigation and sustainable development. Governance interventions to implement the SDGs will need to be operationalised at sub-national, national and global levels and support integration of resource concerns in policy, planning and implementation (UNEP 2015; Williams et al. 2020).

Cross-Chapter Box 12 | Transition Dynamics

Authors: Anthony Patt (Switzerland), Heleen de Coninck (the Netherlands), Xuemei Bai (Australia), Paolo Bertoldi (Italy), Sarah Burch (Canada), Clara Caiafa (Brazil/the Netherlands), Felix Creutzig (Germany), Renée van Diemen (the Netherlands/United Kingdom), Frank Geels (United Kingdom/the Netherlands), Michael Grubb (United Kingdom), María Josefina Figueroa Meza (Venezuela/Denmark), Şiir Kilkış (Turkey), Jonathan Köhler (Germany), Catherine Mitchell (United Kingdom), Lars J. Nilsson (Sweden), Patricia Perkins (Canada), Yamina Saheb (France/Algeria), Harald Winkler (South Africa)

Introduction

Numerous studies suggest that transformational changes would be required in many areas of society if climate change is to be limited to 2°C warming or less. Many of these involve shifts to low-carbon technologies, such as renewable energy, which typically involve changes in associated regulatory and social systems; others more explicitly concern behavioural shifts, such as towards plant-based diets or cleaner cooking fuels, or, at the broadest level, a shift in development pathways. Chapter 1 establishes an analytic framework focusing on transitions, which chapters 5, 13, 14, 15 and 16 further develop. In this Cross-Chapter Box, we provide a complementary overview of the dynamics of different kinds of transformational changes for climate mitigation and sustainable development. We first focus on insights from socio-technical transitions approaches, and then expand to broader system transitions.

Dynamics of socio-technical transitions

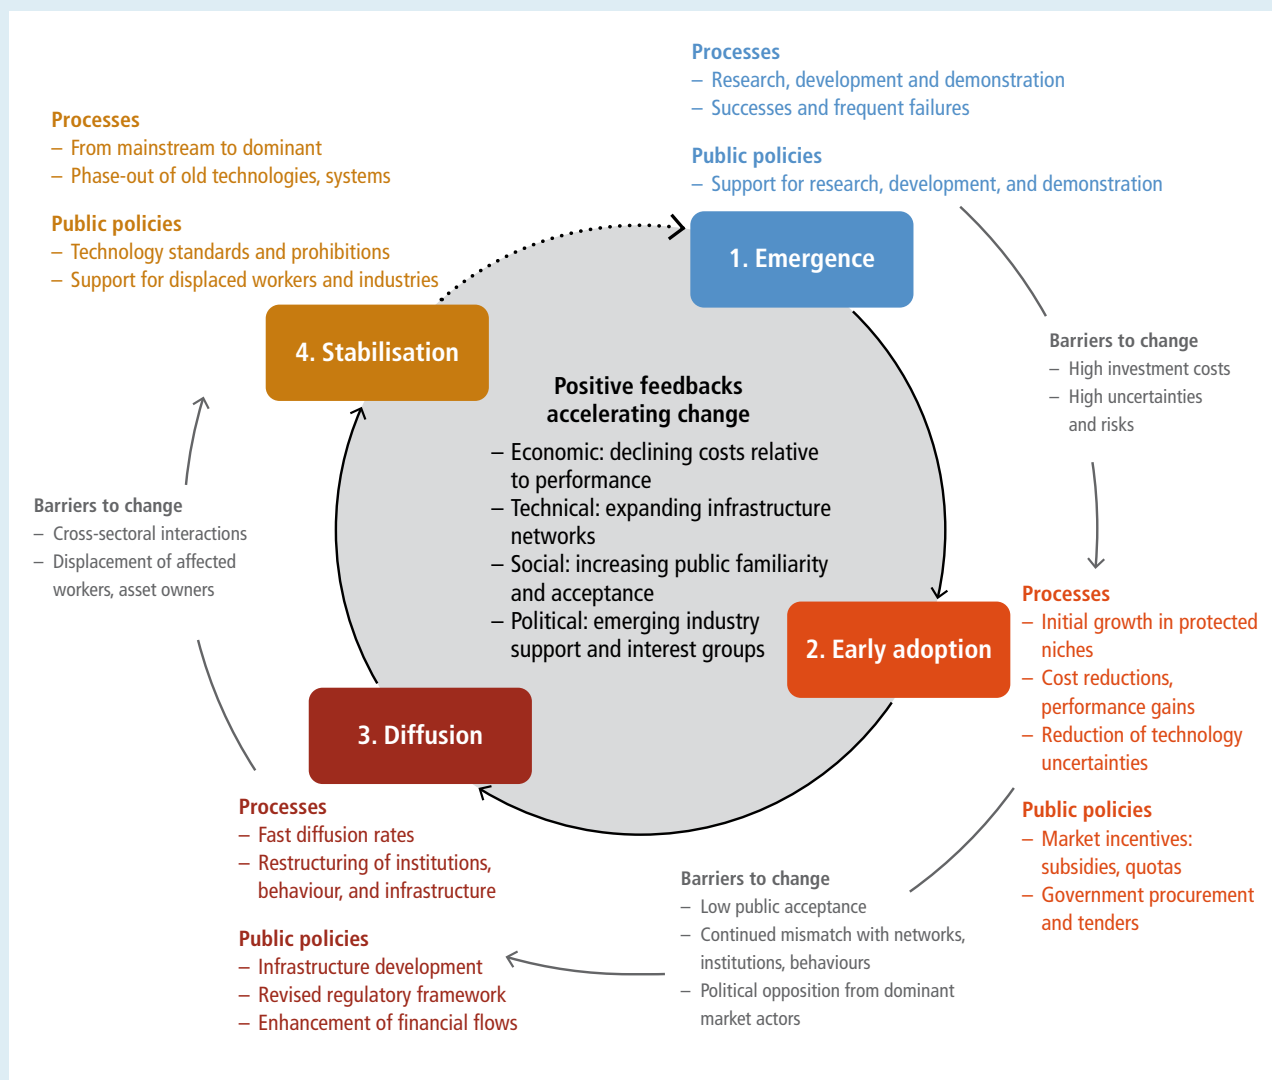

A large volume of literature documents the processes associated with transformational changes in technology and the social systems associated with their production and use (Geels 2019; Köhler et al. 2019). Transformational technological change typically goes hand in hand with shifts in knowledge, behaviour, institutions, and markets (Geels and Schot 2010; Markard et al. 2012); stickiness in these

Cross-Chapter Box 12 (continued)

factors often keeps society 'locked in' to those technologies already in widespread use, rather than allowing a shift to new ones – even those that offer benefits (David 1985; Arthur 1994). Exceptions often follow consistent patterns (Geels 2002; Unruh 2002); since AR5 a growing number of scholars have suggested using these insights to design more effective climate policies and actions (Geels et al. 2017). Chapter 1 (Section 1.7 and Figure 1.6) represents technology diffusion and a corresponding shift in policy emphasis as a continuous process; it is also useful to identify a sequence of distinct stages that typically occur, associating each stage with a distinct set of processes, challenges, and effective policies (Patt and Lilliestam 2018; Victor et al. 2019). Consistent with elsewhere in this report (Section 5.5.2 and Supplementary Material 5.5.3 in Chapter 5, and Section 16.3 in Chapter 16), Cross-Chapter Box 12 Figure 1 elaborates on four distinct stages: it portrays these as occurring in a cycle, recognising that even transformative technologies will eventually be replaced with newer ones.

The *emergence* stage is marked by experimentation, innovation in the laboratory, and demonstration in the field, to produce technologies and system architectures (Geels 2005). By its very nature, experimentation includes both successes and failures, and implies high risks. Because of these risks, especially in the case of fundamentally new technologies, government funding for research, development and demonstration (RD&D) projects is crucial to sustaining development (Mazzucato 2015b).

The second stage is *early adoption*, during which successful technologies jump from the laboratory to limited commercial application (Pearson and Foxon 2012). Reaching this stage is often described as crossing the 'Valley of Death', because the cost/performance ratio

Cross-Chapter Box 12, Figure 1 | Stages of socio-technical transition processes.

Cross-Chapter Box 12 (continued)

for these new market entrants is too low for them to appear viable to investors (Murphy and Edwards 2003). A key process in the early adoption phase is induced innovation, a result of incremental improvements in both design and production processes, and of mass-production of a growing share of key components (Nemet 2006; Grubb et al. 2021). There is diversity across classes of technologies, and learning tends to occur faster for technologies that are modular (Wilson et al. 2020) – such as photovoltaics – and slower for those that require site- or context-specific engineering, such as in the shift to low-carbon materials production (Malhotra and Schmidt 2020). Public policies that create a secure return on investment for project developers can lead to learning associated with industry expansion (Chapter 16, Figure 16.1); typically these are economically and politically viable when they promote growth within a market niche, causing little disruption to the mainstream market (Roberts et al. 2018). Direct support mechanisms are effective, including cross-subsidies (such as feed-in tariffs) and market quotas (such as renewable portfolio standards) (Geels et al. 2017b; Patt and Lilliestam 2018; and Chapter 9 for assessment of early adoption policies in the building sector). The value of these policies is less in their immediate emissions reductions, but more in generating the conditions for self-sustaining transformational change to take place as technologies later move from niche to mainstream (Hanna and Victor 2021).

The third stage, *diffusion*, is where niche technologies become mainstream, with accelerating diffusion rates (Sections 1.7 and 16.4), and is marked by changes to the socio-technical 'regime', including infrastructure networks, value chains, user practices, and institutions. This stage is often the most visible and turbulent, because more widespread adoption of a new technology gives rise to structural changes in institutions and actors' behaviour (e.g., increased adoption of smartphones to new payment systems and social media), and because when incumbent market actors become threatened, they often contest policies promoting the new technologies (Köhler et al. 2019). In the diffusion stage, policy emphasis is shifted from financial support during the early adoption stage, towards supporting regime-level factors needed to sustain, or cope with, rapid and widespread diffusion (Markard 2018). These factors and policies are context specific. For example, Patt et al. (2019) document that the policies needed to expand residential charging networks for electric vehicles depend on the local structure of the housing market.

The fourth stage is *stabilisation*, in which the new technologies, systems, and behaviours are both standardised and insulated from rebound effects and backsliding (Andersen and Gulbrandsen 2020). Sectoral bans on further investment in high-carbon technologies may become politically feasible at this point (Breetz et al. 2018; Economidou et al. 2020). The decline of previously dominant products or industries can lead to calls for policymakers to help those negatively affected, enabling a just transition (McCauley and Heffron 2018; Newell and Simms 2020). Political opposition to the system reconfiguration that comes with integration and stabilisation can also be overcome by offering incumbent actors an attractive exit strategy (de Gooyert et al. 2016).

Because different sectors are at different stages of low-carbon transitions, and because the barriers that policies need to address are stage- and often context-specific, effective policies stimulating socio-technical transitions operate primarily at the sectoral level (Victor et al. 2019). This is particularly the case during early adoption, where economic barriers predominate; during diffusion, policies that address regime-level factors often need to deal with cross-sectoral linkages and coupling, such as those between power generation, transportation, and heating (Patt 2015; Bloess 2019; Fridgen et al. 2020). The entire cycle can take multiple decades. However, later stages can go faster by building on the earlier stages that have taken place elsewhere. For example, early RD&D into wind energy took place primarily in Denmark, was followed by early adoption in Denmark, Germany, and Spain, before other countries, including the USA, India, and China, leapfrogged directly to the diffusion stage (Chaudhary et al. 2015; Dai and Xue 2015; Lacal-Arántegui 2019). A similar pattern played out for solar power (Nemet 2019). International cooperation, geared towards technology transfer, capacity and institution-building, and finance, can help ensure that developing countries leapfrog to low-carbon technologies that have undergone commercialisation elsewhere (Adenle et al. 2015; Fankhauser and Jotzo 2018) (see also Chapter 5, Box 5.9, Chapter 15, Section 15.5, and Section 16.5 in this chapter).

This report contains numerous examples of the positive feedbacks in the centre of Cross-Chapter Box 12, Figure 1, predominantly arising during the early adoption and diffusion stages, and leading to rapid or unexpected acceleration of change. For example, public acceptance of meat alternatives leads to firms improving the products, increasing political and economic feedbacks (Section 5.4 and Box 5.5). Declining costs in solar and wind cause new investment in the power-generation sector being dominated by those technologies, leading to increased political support and further cost reductions (Chapter 6). In buildings (Chapter 9) and personal mobility (Chapter 10), low-carbon heating systems and electric vehicles are gaining public acceptance, leading to improved infrastructure and human resources, more employment in those sectors, and behavioural contagion. Some have argued that technologies cross societal tipping points on account of these feedbacks (Obama 2017; Sharpe and Lenton 2021).

Dynamics between enabling conditions for system transitions

Abson et al. (2017) argue that it is possible to make use of 'leverage points' inherent in system dynamics in order to accelerate sustainability transitions. Otto et al. (2020) argue that interventions geared towards the social factors driving change can 'activate

Cross-Chapter Box 12 (continued)

contagious processes' leading to the transformative changes required for climate mitigation. These self-reinforcing dynamics involve the interaction of enabling conditions, including public policy and governance, institutional and technological innovation capacity, behaviour change, and finance. For example, Mercure et al. (2018) simulated financial flows into fossil-fuel extraction, and showed how investors taking into account transition risk in combination with technological innovation would lead to the enhancement of investments in low-carbon assets and further enhanced innovation. As another example, behaviour, lifestyle, and policy can also initiate demand-side transitions (Tziva et al. 2020) (Chapter 5), such as with food systems (Rust et al. 2020) (Section 7.4.5), and can contribute to both resilience and carbon storage (Sendzimir et al. 2011) (Box 16.5).

In the urban context, the concept of sustainability experiments has been used to examine innovative policies and practices adopted by cities that have significant impact on transition towards low-carbon and sustainable futures (Bai et al. 2010; Castán Broto and Bulkeley 2013). Individual innovative practices can potentially be upscaled to achieve low-carbon transition in cities (Peng and Bai 2018), leading to a process of broadening and scaling innovative practices in other cities (Peng et al. 2019). Such sustainability experiments give rise to new actor networks, which in some cases may accelerate change, and in others may lead to conflict (Bulkeley et al. 2014). As in the diffusion phase in Cross-Chapter Box 12, Figure 1, contextual factors play a strong role. Examining historical transitions to cycling across European cities, Oldenziel et al. (2016) found that contextual factors, including specific configurations of actors, can lead to very different outcomes. Kraus and Koch (2021) found a short-term social shock – such as the COVID-19 crisis – to lead to differential increases in cycling behaviour, contingent on other enabling conditions.

Linking system dynamics to development pathways and broader societal goals

Transition dynamics insights can be broadened to shifting development pathways. Development paths are characterised by particular sets of interlinking regime rules and behaviours, including inertia and cascading effects over time, and are reinforced at multiple levels, with varied capacities and constraints on local agency occurring at each level (Burch et al. 2014) (Cross-Chapter Box 5 in Chapter 4). This is also observed by Schot and Kanger (2018), who identify a needed change in a 'meta-regime', crossing sectoral lines in linking value chains or infrastructure and overall development objectives. In the context of the UN climate change regime, international cooperation can bring together such best practices and lessons learnt (Adenle et al. 2015; Pandey et al. 2021). This is especially relevant for developing countries, which often depend on technologies and financial resources from abroad, witnessing their pace and direction influenced by transnational actors (Marquardt et al. 2016; Bhamidipati et al. 2019), and benefitting little in terms of participating in high value-added activities (Whittaker et al. 2020).

System transitions differ according to context, such as across industrialised and developing countries (Ramos-Mejía et al. 2018), and within countries. Lower levels of social capital and trust negatively impact niche commercialisation (Lepoutre and Oguntoye 2018). In contexts of poverty and inequality, stakeholders' – including users' – capabilities for meaningful participation are limited, and transition outcomes can end up marginalising or further excluding social groups (Osongo and Schot 2017; Hansen et al. 2018). Many studies of transitions in developing countries make note of the importance of innovation in the informal sector (Charmes 2016) (Box 5.10 in Chapter 5). Facilitating informal sector access to renewable energy sources, safe and sustainable buildings, and finance can advance low-carbon transitions (McCauley et al. 2019; Masuku and Nzewi 2021). On the contrary, disregarding its importance can result in misleading or ineffective innovation and climate strategies (Maharajh and Kraemer-Mbula 2010; Mazhar and Ummad 2014; de Beer et al. 2016; Masuku and Nzewi 2021).

Policies shifting innovation in climate-compatible directions can also reinforce other development benefits, for instance better health, increased energy access, poverty alleviation and economic competitiveness (Deng et al. 2018; IPCC 2018a; Karlsson et al. 2020). Development benefits, in turn, can create feedback effects that sustain public support for subsequent policies, and hence help to secure effective long-term climate mitigation (Geels 2014; Meckling et al. 2015; Schmidt and Sewerin 2017; Breetz et al. 2018), increasing legitimacy of environmental sustainability actions (Hansen et al. 2018; Herslund et al. 2018; van Welie and Romijn 2018) and addressing negative socio-economic impacts (Deng et al. 2018; McCauley and Heffron 2018; Eisenberg 2019; Henry et al. 2020).

Summary and gaps in knowledge

Strategies to accelerate climate mitigation can be most effective at accelerating and achieving transformative change when they are synchronised with transition processes in systems. They address technological stage characteristics, take advantage of high-leverage intervention points, and respond to societal dynamics (Abson et al. 2017; Geels et al. 2017; Köhler et al. 2019). Gaps in knowledge remain on how to tailor policy mixes, the interaction of enabling conditions, the generalisability of socio-technical transition insights to other types of systems, and how to harness these insights to better shift development pathways.

16.6.2 Sustainable Development and Technological Innovation: Synergies, Trade-offs and Governance

16.6.2.1 Synergies and Trade-offs

Policies that shift innovation in climate compatible directions can promote other development benefits, for instance, better health, increased energy access, poverty alleviation and economic competitiveness (Deng et al. 2018) (Cross-Chapter Box 12). Economic competitiveness co-benefits can emerge as climate mitigation policies trigger innovation that can be leveraged for promoting industrial development, job creation and economic growth, both in terms of localising low-emission energy technologies value chains as well as increased energy efficiency and avoided carbon lock-ins (Section 16.4). However, without adequate capabilities, co-benefits at the local level would be minimal, and they would probably materialise far from where activities take place (Ockwell and Byrne 2016; Vasconcellos and Caiado Couto 2021). Innovation and technological change can also empower citizens. Grass-roots innovation promotes the participation of grass-roots actors, such as social movements and networks of academics, activists and practitioners, and facilitate experimenting with alternative forms of knowledge creation (Seyfang and Smith 2007; UNCTAD 2019). Examples of ordinary people and entrepreneurs adopting and adapting technologies to local needs to address locally defined needs have been documented in the development literature (van Welie and Romijn 2018) (Box 16.10). Digital technologies can empower citizens and communities in decentralised energy systems, contributing not only to a more sustainable but also to a more democratic and fairer energy system (Van Summeren et al. 2021) (Section 5.4 in Chapter 5, and Cross-Chapter Box 11 in this chapter).

Therefore, even though science, technology and innovation is an explicit focus of SDG 9, it is an enabler of most SDGs (UNCTAD 2019). Striving for synergies between innovation and technological change for climate change mitigation with other SDGs can help to secure effective long-term climate mitigation, as development benefits can create feedback effects that sustain public and political support for subsequent climate mitigation policies (Geels 2014; Meckling et al. 2015; Cross-Chapter Box 12 in this chapter). However, innovation is not always geared to sustainable development – for instance, firms tend to know how to innovate when value chains are left intact (Hall and Martin 2005), which is usually not the case in systemic transitions.

A comprehensive study of these effects distinguishes among ‘... anticipated-intended, anticipated-unintended, and unanticipated-unintended consequences’ (Tonn and Stiefel 2019). Theoretical and empirical studies have demonstrated that unintended consequences are typical of complex adaptive systems, and while a few are predictable, a much larger number are not (Sadras 2020). Even when unintended consequences are unanticipated, they can be prevented through actor responses, for instance, rebound effects following the introduction of energy-efficient technologies. Other examples of unintended consequences include worse-than-expected physical damage to infrastructure and resistance from communities in the rapidly growing ocean renewable energy sector (Quirapas and

Taeihagh 2020), and gaps between expected and actual performance of building-integrated photovoltaic (BIPV) technology (Boyd and Schweber 2018; Gram-Hanssen and Georg 2018). In the agricultural sector, new technologies and associated practices that target the fitness of crop pests have been found to favour resistant variants. Unintended consequences of digitalisation are reported as well (Lynch et al. 2019) (Cross-Chapter Box 11 in this chapter).

Innovation and climate mitigation policies can also have negative socio-economic impacts, and not all countries, actors and regions around the world benefit equally from rapid technological change (Deng et al. 2018; McCauley and Heffron 2018; Eisenberg 2019; UNCTAD 2019; Henry et al. 2020). In fact, socio-technical transitions often create winners and losers (Roberts et al. 2018). Technological change can reinforce existing divides between women and men, rural and urban populations, and rich and poor communities: older workers displaced by technological change will not qualify for jobs if they were unable to acquire new skills; weak educational systems may not prepare young people for emerging employment opportunities; and disadvantaged social groups, including women in many countries, often have fewer opportunities for formal education (McCauley and Heffron 2018; UNCTAD 2019). That is a risk regarding technological change for climate change mitigation, as emerging evidence suggests that the energy transition can create jobs and productivity opportunities in the renewable energy sector, but will also lead to job losses in fossil fuel and exposed sectors (Le Treut et al. 2021). At the same time, these new jobs may use more intensively high-level cognitive and interpersonal skills compared to regular, traditional jobs, requiring higher levels of human capital dimensions such as formal education, work experience and on-the-job training (Consoli et al. 2016). Despite the empowerment potentials of decentralised energy systems, not all societal groups are equally positioned to benefit from energy community policies, with issues of energy justice taking place within initiatives, between initiatives and related actors, as well as beyond initiatives (Calzadilla and Mauger 2018; van Bommel and Höffken 2021).

The opportunities and challenges of technological change can also differ within country regions and between countries (Garcia-Casals et al. 2019). Within countries, Vasconcellos and Caiado Couto (2021) show that, in the absence of policies and capacity-building activities which promote local recruiting, a significant part of total benefits of wind projects, especially high-income jobs and high value-added activities, is captured by already higher-income regions. Between countries, developing countries usually have lower innovation capabilities, which means they need to import low-emission technology from abroad and are also less able to adapt these technologies to local conditions and create new markets and business models. This can lead to external dependencies and limit opportunities to leverage economic benefits from technology transfer (Section 16.5.1).

This means that, in countries below the technological frontier, the contribution of technological change to climate change mitigation can happen primarily through the adoption and less through the development of new technologies, which can reduce potential

economic and welfare benefits from rapid technological change (UNCTAD 2019). The adoption of consumer information and communication technology (ICT) (Baller et al. 2016) or renewable energy technology (Lema et al. 2021) cannot bring least-developed economies close to the technological frontier without appropriate technological capabilities in other sectors, and an enabling innovation system (Ockwell and Mallett 2012; Sagar and Majumdar 2014; Ockwell et al. 2018; UNCTAD 2019; Malhotra et al. 2021; Vasconcellos and Caiado Couto 2021). It has been argued widely that both hard and soft infrastructure, as well as appropriate policy frameworks and capability building, would facilitate developing countries' engagement in long-term technological innovation and sustainable industrial development, and eventually in achieving the SDGs (Ockwell and Byrne 2016; Altenburg and Rodrik 2017; UNCTAD 2019).

16.6.2.2 Challenges to Governing Innovation for Sustainable Development

Dominant economic systems and centralised governance structures continue to reproduce unsustainable patterns of production and consumption, reinforcing many economic and governance structures from local through national and global scales (Johnstone and Newell 2018). Technological change, as an inherently complex process (Funtowicz 2020), poses governance challenges (Bukkens et al. 2020) requiring social innovation (Repo and Matschoss 2019) (Section 5.6 and Chapter 13).

Prospects for effectively governing SDG-oriented technological transformations require, at a minimum, balanced views and new tools for securing the scientific legitimacy and credibility to connect public policy and technological change in society (Jasanoff 2018; Sadras 2020). Many frameworks of governance have been proposed, such as reflexive governance (Voss et al. 2006), polycentric governance (Ostrom 2010), collaborative governance (Bodin 2017), adaptive governance (Munene et al. 2018) and transformative governance (Rijke et al. 2013; Westley et al. 2013) (Chapters 13 and 14).

A particular class of barriers to the development and adoption of new technologies comprises entrenched power relations dominated by vested interests that control and benefit from existing technologies (Chaffin et al. 2016; Dorband et al. 2020). Such interests can generate balancing feedbacks within multilevel social-technological regimes that are related to technological lock-in, including allocations of investment between fossil and renewable energy technologies (Unruh 2002; Sagar et al. 2009; Seto et al. 2016).

Weaker coordination and implementation capacity in some developing countries can undermine the ability to avoid trade-offs with other development objectives – such as reinforced inequalities or excessive indebtedness and increased external dependency – and can limit the potential of leveraging economic benefits from technologies transferred from abroad (Section 16.5 and Cross-Chapter Box 12 in this chapter). Van Welie and Romijn (2018) show that, in a low-income setting, the exclusion of some local stakeholders from the decision-making process may undermine sustainability transitions efforts. Countries with high levels of inequality can be more prone to elite capture, non-transparent political decision-making processes,

relations based on clientelism and patronage, and no independent judiciary (Jasanoff 2018), although in particular contexts, non-elites manage to exert influence (Moldaliev and Heathershaw 2020). The dominance of incumbents, however, implies that sustainable technological transitions could be achieved without yielding any social and democratic benefits (Hansen et al. 2018). In the cultural domain, a recurrent policy challenge that has been observed in most countries is the limited public support for development and deployment of low-carbon technologies (Bernauer and McGrath 2016). The conventional approach to mobilising such support has been to portray technological change as a means of minimising climate change. Empirical studies show that simply reframing climate policy is highly unlikely to build and sustain public support (Bernauer and McGrath 2016).

Finally, there is a link between social and technological innovation; any innovation is grounded in complex socio-economic arrangements, to which governance arrangements would need to respond (Sections 5.5 and 5.6, Chapter 13, and Cross-Chapter Box 12 in this chapter). Social innovation can contribute to maximising synergies and minimising trade-offs in relation to technological and other innovative practices, but for this to materialise, national, regional and local circumstances need to be taken into account and, if needed, changed. Even in circumstances of high capabilities, the extent that social innovation might help to promote synergies and avoid trade-offs is not easy to evaluate (Grimm et al. 2013).

16.6.3 Actions that Maximise Synergies and Minimise Trade-offs Between Innovation and Sustainable Development

Technological innovation may bring significant synergy in pursuing SDGs, but it may also create challenges to the economy, human well-being, and the environment (Schillo and Robinson 2017; Thacker et al. 2019; Walsh et al. 2020). The degree of potential synergies and trade-offs among SDGs differs from country to country and over time (Section 16.6.1.1). These potentials will depend on available resources, geographical conditions, development stage and policy measures. Even though synergies and trade-offs related to technological innovation have received the least attention from researchers (Deng et al. 2018), literature show that higher synergy was found where countries' policies take into account the linkages between sectors (Mainali et al. 2018). For technology innovation to be effective in enhancing synergies and reducing trade-offs, its role and nature in production and consumption patterns, as well as in value chains and in the wider economy, requires clarification. Technology ownership and control together with its current orientation and focus towards productivity, needs to be revised if a meaningful contribution to the implementation of the SDGs is to be achieved in a transformative way (Walsh et al. 2020). Responsible innovation, combining anticipation, reflexivity, inclusion and responsiveness, has been suggested as a framework for conducting innovation (Stilgoe et al. 2013). Also inclusive innovation (Hoffecker 2021) could make sure that unheard voices and interests are included in decision-making, and that methods for this have been implemented in practice (Douthwaite and Hoffecker 2017).

There are several examples of how to maximise synergies and avoid or minimise trade-offs when bringing technological innovation to the ground. When implementing off-grid solar energy in Rwanda, synergies were found between 80 of the 169 SDG targets, demonstrating how mainstreaming off-grid policies and prioritising investment in the off-grid sector can realise human development and well-being, build physical and social infrastructures, and achieve sustainable management of environmental resources (Bisaga et al. 2021). Another example is related to wind power in Northeast of Brazil where the creation of direct and indirect jobs has been demonstrated in areas where capabilities are high, as well as associated improvements in wholesale and retail trade and real estate activities, though this also emphasises the need for capacity development along with international collaboration projects (Vasconcellos and Caiado Couto 2021). Other examples include studies raising awareness on solar energy and women's empowerment (Winther et al. 2018) and recycling and waste (Cross and Murray 2018).

Other actions with the potential to maximise synergies are those related to community or grassroots technological innovation. The

importance of the link between technological innovation and community action and its contribution to sustainable development is usually underestimated. Further research is needed on this and, most importantly, its inclusion in the political agenda on sustainable development (Seyfang and Smith 2007). On the other hand, when technological innovation occurs far from where is implemented and participation in the production, and hence training activities of local actors is minimal, co-benefits and synergies among SDGs are limited and usually far below expectations (Bhamidipati and Hansen 2021; Vasconcellos and Caiado Couto 2021). Actions by policymakers that safeguard environmental and social aspects can boost synergies and maximise those co-benefits (Lema et al. 2021). Given that technological change impacts countries, regions and social groups differently, transition policies can be designed to ensure that all regions and communities are able to take advantage of the energy and other transitions (McCauley and Heffron 2018; Henry et al. 2020).

Box 16.10 provides insights on how a systemic approach to technological innovation can contribute to reconcile synergies and trade-offs to achieve sustainable development and mitigation goals.

Box 16.10 | Agroecological Approaches: The Role of Local and Indigenous Knowledge and Innovation

Major improvements in agricultural productivity have been recorded over recent decades (FAO 2018a). However, progress has also come with social and environmental costs, high levels of greenhouse gas (GHG) emissions, and rising demand for natural resources (UNEP 2013; UNEP 2017; FAO 2018a; Bringezu 2019; Díaz et al. 2019).

Trend analysis indicates that a large share of the global demand for land is projected to be supplied by South America, in particular the Amazon (Lambin and Meyfroidt 2011; TEEB 2018) and Gran Chaco forests (Grau et al. 2015). In developing countries, land use change for satisfying international meat demand is leading to deforestation. In Brazil, the amount of GHGs emitted by the beef cattle sector alone represents 65% of the agricultural sector's emissions and 15% of the country's overall emissions (May 2019).

Agricultural and food systems are complex and diverse; they include traditional food systems, mixed food systems and modern food systems (Pengue et al. 2018). Multiple forms of visible and invisible flows of natural resources exist in global food systems (Pascual et al. 2017; TEEB 2018; IPBES 2019).

Technological practices, management and changes in the food chain could help adapt to climate change, reduce emissions and absorb carbon in soil, thus contributing to carbon dioxide removal (IPCC, 2018, 2019). A range of technologies can be implemented – from highly technological options, such as transgenic crops resistant to drought (González et al. 2019), salt or pesticides (OECD 2011b; Kim and Kwak 2020) or smart and 4.0 agriculture (Klerkx et al. 2019), to more frugal, low-cost technologies such as agroecological approaches adapted to local circumstances (Francis et al. 2003; FAO 2018b). These agroecological approaches are the subject of this box.

For developing countries, agroecological approaches could tackle climate change challenges and food security (WGII-report, Chapter 5, Box 5.10). Small Island Developing States (SIDS) support livelihoods to develop local food value chains that can promote sustainable management of natural resources, preserve biodiversity and help build resilience to climate change impacts and natural disasters (FAO 2019). Other advantages of agroecological practices include their adaptation to different social, economic and ecological environments (Altieri and Nicholls 2017), the fact that they are physical and financial capital-extensive, and are well-integrated with the social and cultural capital of rural territories and local resources (knowledge, natural resources, etc.), without leading to technological dependencies (Côte et al. 2019).

Agroecology is a dynamic concept that has gained prominence in scientific, agricultural and political discourses in recent years (Wezel et al. 2020; Anderson et al. 2021) (Chapter 7, Chapter 5, WGII Box 5.10). Three of the different agroecological approaches are briefly discussed here: agroecological intensification; agroforestry; and biochar use in rice paddy fields.

Box 16.10 (continued)

Agricultural intensification provides ways to use land, water and energy resources to ensure adequate food supply while also addressing concerns about climate change and biodiversity (Cassman and Grassini 2020). The term ecological intensification (Tittonell 2014) focuses on biological and ecological processes and functions in agroecosystems. In line with the development of the concept of agroecology, agroecological intensification integrates social and cultural perspectives (Wezel et al. 2015). Agroecological intensification (Mockshell and Villarino 2019) for sub-Saharan Africa aims to address employment and food security challenges (Pretty et al. 2011; Altieri et al. 2015).

Another example of an agroecological approach is agroforestry. Agroforestry provides examples of positive agroecological feedbacks, such as ‘the greening of the Sahel’ in Niger. The practice is based on the assisted natural regeneration of trees in cultivated fields, an old method that was slowly dying out, but which innovative public policies (the transfer of property rights over trees from the state to farmers) helped restore (Sendzimir et al. 2011).

Rice paddy fields are a major source of methane. Climate change impacts and adaptation strategies can affect rice production and rice farmers’ net income. Biochar use in rice paddy fields has been advocated as a potential strategy to reduce GHG emissions from soils, enhance soil carbon stocks and nitrogen retention, and improve soil function and crop productivity (Mohammadi et al. 2020).

The contributions of indigenous people (Díaz et al. 2019), heritage agriculture (Koochafkan and Altieri 2010) and peasants’ agroecological knowledge (Holt-Giménez 2002) to technological innovation offer a wide array of options for management of land, soils, biodiversity and enhanced food security without depending on modern, foreign agricultural technologies (Denevan 1995). In farming agriculture and food systems, innovation and technology based on nature could help to reduce climate change impacts (Griscom et al. 2017). Evidence suggests that there are benefits to integrating tradition with new technologies in order to design new approaches to farming, and that these are greatest when they are tailored to local circumstances (Nicholls and Altieri 2018).

16.6.4 Climate Change, Sustainable Development and Innovation

This section gives a synthesis of this chapter on innovation and technology development and transfer, connecting it to sustainable development.

In conjunction with other enabling conditions, technological innovation can support system transitions to limit warming, help shift development pathways, and bring about new and improved ways of delivering goods and services that are essential to human well-being (*high confidence*). At the same time, however, innovation can result in trade-offs that undermine progress on mitigation and towards other SDGs. Trade-offs include negative externalities, such as environmental impacts and social inequalities, rebound effects leading to lower net emission reductions or even increases in emissions, and increased dependency on foreign knowledge and providers (*high confidence*). Digitalisation, for example, holds both opportunity for emission reduction and emission-saving behaviour change, but at the same time causes significant environmental, social and greenhouse gas (GHG) impacts (*high confidence*).

A systemic view of innovation that takes into account the roles of actors, institutions, and their interactions, can contribute to enhanced understanding of processes and outcomes of technological innovation, and to interventions and arrangements that can help innovation. It can also play a role in clarifying the synergies and trade-offs between technological innovation and the SDGs. Effective governance and policy, implemented in an inclusive, responsible and

holistic way, could make innovation policy more effective, and avoid and minimise misalignments between climate change mitigation, technological innovation, and other societal goals (*medium evidence, high agreement*).

A special feature is the dynamics of transitions. Like other enabling conditions, technological innovation plays a balancing role – by inhibiting change as innovation strengthens incumbent technologies and practices – and a reinforcing role, by allowing new technologies and practices to disrupt the existing socio-technical regimes (*high confidence*). Appropriate innovation policies can help to better organise innovation systems, while other policies (technology push and demand pull) can provide suitable resources and incentives to support and guide these innovation systems towards societally-desirable outcomes, ensure the innovations are deployed at scale, and direct these dynamics towards system transitions for climate change mitigation, and also towards addressing other SDGs. This means taking into account the full lifecycle or value chain as well as analysis of synergies and trade-offs.

Against this backdrop, international cooperation on technological innovation is one of the enablers of climate action in developing countries on both mitigation and adaptation (*high confidence*). Experiences with international cooperation on technology development and deployment suggest that such activities are most effective when they: are approached as ‘innovation cooperation’ that engenders a holistic, systemic view of innovation requirements; are an equitable partnership between donors and recipients; and develop local innovation capabilities (*medium evidence, high agreement*).

Chapter 17, in particular Section 17.4, connects technological innovation with other enabling conditions, such as behaviour, institutional capacity and multilevel governance, to clarify the actions that could be taken, holistically and in conjunction, to strengthen and accelerate the system transitions required to limit warming to be in line with the Paris Agreement and to place countries in sustainable development pathways.

16.7 Knowledge Gaps

Filling gaps in literature availability, data collection, modelling, application of frameworks and further analysis in several sectors will improve knowledge on innovation and technology development and transfer, including research and development (R&D) to support policymaking in climate change mitigation as well as adaptation. These policies and related interventions need to benefit from data and methodologies for the *ex post* evaluation of their effectiveness.

This section addresses identified knowledge gaps related to: what extent developing countries are represented in studies on innovation and technology development and transfer; national contexts and local innovation capacity; potential and actual contributions of businesses; literature emphasis on mitigation; indicators to assess innovation systems; non-technical barriers for the feasibility of decarbonisation pathways; the role of domestic intellectual property rights (IPR) policy; digitalisation in low-emissions pathways; and Paris Agreement compliance regarding technology and capacity building.

Representation of developing countries

One of knowledge gaps identified when assessing the literature is on the representation of developing countries in studies on innovation and technology development and transfer. This includes the conceptual core disciplines of the economics of innovation, innovation systems and sustainability transitions. This is true for studies on developing countries, and for authors originating from, or active in, developing country contexts. The evidence of the impact of decarbonisation policy instruments applied to developing countries or Small Island Developing States (SIDS) is limited. Expanding the knowledge base with studies that focus on developing countries would not only allow for testing whether the theories (developed by predominantly by developed-country researchers for industrialised countries) hold in developing country contexts, but also yield policy insights that could help both domestic and international policymakers working on climate-related technology cooperation.

National contexts and local innovation capacity

While a growing body of literature has shown how technology characteristics and complexity, national context and innovation capacity can influence the capacity of a country's innovation ecosystem as a result of incentive and attraction policies, more research is needed to help prioritise and design policies in different

national contexts. Important knowledge gaps need to be filled regarding the impact of 'green' public procurement, lending, 'green' public banking, and building code policies on innovation outcomes.

There is also a superficial understanding of the potential and actual contributions of businesses, educational institutions and socially responsible programmes, particularly in developing countries, as sources of innovation and early adopters of new technologies, and a notable lack of knowledge about indigenous practices.

Emphasis on mitigation

Current literature has a strong bias to studies originating from and based on developed countries. Also, innovation and technology literature is skewed to mitigation and, specifically, energy. Literature on technology innovation for adaptation is largely missing.

In the area of innovation studies, data are limited on the different indicators used to assess the strength of the innovation system, (even for energy), including global figures on R&D and demonstration spending, also for developing countries, and their effectiveness. There is also a lack of a comprehensive framework and detailed data to assess the strengths of low-emission innovation systems, including interactions among actors, innovation policy implementation, and strength of institutions.

Indicators to assess innovation systems

Another gap in knowledge remains between the results from energy-climate-economy models and those emerging from systems and sustainability transition approaches, empirical case studies, and the innovation system literature. If this gap is filled, understanding could be improved of the feasibility of decarbonisation pathways in light of the many non-technical barriers to technology deployment and diffusion.

Non-technical barriers for the feasibility of decarbonisation pathways

In the field of policy instruments, existing evaluations provide insufficient evidence to assess the impact of decarbonisation policy instruments on innovation, as these evaluations mainly focus on environmental or technological effects.

Domestic IPR policy

The potential positive or negative role of domestic IPR policy in technology transfer to least-developed countries remains unclear as the literature does not show agreement. Moreover, gaps remain in impact evaluations of sub-national green industrial policies, which are of growing importance. The interaction between subnational and national decarbonisation policies to advance innovation would also benefit from further research, particularly in developing countries.

Digitalisation in low-emissions pathways and digitalisation

The understanding of the role of digitalisation in decarbonisation pathways is lacking and needs to be studied from several angles. Existing studies do not sufficiently take into account knowledge on the energy impact of digital technologies, in particular the increase in energy demand by digital devices, and the increase in energy efficiency. Studies would benefit from being technology/sector/country-specific.

Further exploration is needed into the way digitalisation influences the framework conditions that cause decarbonisation, the socio-economic and behavioural barriers influencing the diffusion of technologies in the long-term scenarios, and the relationship with society and its effects.

Given the implications of the digital revolution for sustainability, a better characterisation of governance aspects would increase understanding of the implications for policymakers of digitalisation and the possibilities for it and other general-purpose technologies.

Research (theoretical and empirical) on the impacts of imitation, or adaptation of new technological solutions invented in one region and used in other regions, could fill knowledge gaps and accelerate diffusion of climate-related technologies, while taking care not to reduce the incentive for inventors to search for new solutions.

Paris Agreement compliance

An independent assessment is underway to look at the compliance of the Paris Agreement with regard to technology and capacity building as means of implementation. The Enhanced Transparency Framework for action and support is developing a methodology for monitoring, reporting and verification. There is a lack of analysis of the full landscape of international cooperation, of the effectiveness of the UN Framework Convention on Climate Change (UNFCCC) and the Paris Agreement, and what is needed to meet their objectives.

Frequently Asked Questions (FAQs)

FAQ 16.1 | Will innovation and technological changes be enough to meet the Paris Agreement objectives?

The Paris Agreement stressed the importance of development and transfer of technologies to improve resilience to climate change and to reduce greenhouse gas emissions. However, innovation and even fast technological change will not be enough to achieve Paris Agreement mitigation objectives. Other changes are necessary across the production and consumption system and the society in general, including behavioural changes.

Technological changes never happen in a vacuum; they are always accompanied by, for instance, people changing habits, companies changing value chains, or banks changing risk profiles. Therefore, technological changes driven by holistic approaches can contribute to accelerate and spread those changes towards the achievement of climate and sustainable development goals.

In innovation studies, such systemic approaches are said to strengthen the functions of technological or national innovation systems, so that climate-friendly technologies can flourish. Innovation policies can help respond to local priorities and prevent unintended and undesirable consequences of technological change, such as unequal access to new technologies across countries and between income groups, environmental degradation and negative effects on employment.

FAQ 16.2 | What can be done to promote innovation for climate change and the widespread diffusion of low-emission and climate-resilient technology?

The speed and success of innovation processes could be enhanced with the involvement of a wider range of actors from the industry, research and financial communities working in partnerships at national, regional and international levels. Public policies play a critical role to bring together these different actors and create the necessary enabling conditions, including financial support, through different instruments as well as institutional and human capacities.

The increasing complexity of technologies requires cooperation if their widespread diffusion is to be achieved. Cooperation includes the necessary knowledge flow within and between countries and regions. This knowledge flow can take the form of exchanging experiences, ideas, skills, and practices, among others.

FAQ 16.3 | What is the role of international technology cooperation in addressing climate change?

Technologies that are currently known but not yet widely used need to be spread around the world, and adapted to local preferences and conditions. Innovation capabilities are required not only to adapt new technologies for local use, but also to create new markets and business models. International technology cooperation can serve that purpose.

In fact, evidence shows that international cooperation on technology development and transfer can help developing countries to achieve their climate goals more effectively and, if this is done properly, can also help to addressing other sustainable development goals. Many initiatives exist both regionally and globally to help countries in achieving technology development and transfer through partnerships and research collaboration that include developed and developing countries, with a key role for technological institutions and universities. Enhancing current activities would help an effective, long-term global response to climate change, while promoting sustainable development.

Globalisation of production and supply of goods and services, including innovation and new technologies, may open up opportunities for developing countries to advance technology diffusion; however, so far not all countries have benefitted from the globalisation of innovation due to different barriers, such as access to finance and technical capabilities. These asymmetries between countries in the globalisation process can also lead to dependencies on foreign knowledge and providers.

Not all technology cooperation directly results in mitigation outcomes. Overall, technology transfer broadly has focused on enhancing climate technology absorption and deployment in developing countries as well as research, development and demonstration, and knowledge spillovers.

The Paris Agreement also reflects this view by noting that countries shall strengthen cooperative action on technology development and transfer regarding two main aspects: (i) promoting collaborative approaches to research and development; and (ii) facilitating access to technology to developing country Parties.

17.5 Conclusions	1770		

Executive Summary

Accelerating climate actions and progress towards a just transition is essential to reducing climate risks and addressing sustainable development priorities, including water, food and human security (*robust evidence, high agreement*). Accelerating action in the context of sustainable development involves not only expediting the pace of change (speed) but also addressing the underlying drivers of vulnerability and high emissions (quality and depth of change) and enabling diverse communities, sectors, stakeholders, regions and cultures (scale and breadth of change) to participate in just, equitable and inclusive processes that improve the health and well-being of people and the planet. Looking at climate change from a justice perspective means placing the emphasis on (i) the protection of vulnerable populations and low-income countries from the impacts of climate change, (ii) mitigating the effects of the transformations, and (iii) ensuring an equitable decarbonised world. {17.1.1}

While transition pathways will vary across countries, they are likely to be challenging in many contexts (*robust evidence, high agreement*). Climate change is the result of decades of unsustainable production and consumption patterns (for example, energy production and land use), as well as governance arrangements and political economic institutions that lock in resource-intensive development patterns (*robust evidence, high agreement*). Reframing development objectives and shifting development pathways towards sustainability can help transform these patterns and practices, allowing space for transitions to transform unsustainable systems (*medium evidence, high agreement*). {17.1.1.2}

Sustainable development can enhance sectoral integration and social inclusion (*robust evidence, high agreement*). Inclusion merits attention because equity within and across countries is critical to transitions that are not simply rapid but also sustainable and just. Resource shortages, social divisions, inequitable distributions of wealth, poor infrastructure and limited access to advanced technologies can constrain the options and capacities for developing countries to achieve sustainable and just transitions (*medium evidence, high agreement*). {17.1.1.2}

Concrete actions aligning sustainable development and climate mitigation and partnerships can support transitions. Strengthening different stakeholders' 'response capacities' to mitigate and adapt to a changing climate will be critical for a sustainable transition (*robust evidence, high agreement*). Response capacities can be increased by means of alignment across multiple stakeholders at different levels of decision-making. This alignment will also help achieve synergies and manage trade-offs between climate and sectoral policies by breaking down sectoral silos and overcoming the multiple barriers that prevent transitions from gaining traction and gathering momentum (*medium evidence, high agreement*). {17.1.1.1}

Economics, psychology, governance, and systems research have pointed to a range of factors that influence the speed, scale and quality of transitions (*robust evidence, high agreement*).

Views nonetheless differ on how much market-correcting policies; shift preferences (economics); shifts in individual and collective mindsets (psychology); and multi-level governance arrangements and inclusive political institutions (governance) contribute to system transitions (*medium evidence, high agreement*). {17.2}

While economics, psychology, governance and systems thinking emphasise different enablers of transitions, they often share a view that strengthening synergies and avoiding trade-offs between climate and sustainable development priorities can overcome barriers to transitions (*medium evidence, high agreement*). A growing body of research and evidence can show which factors in the views from economics, psychology, governance and systems affect how interrelationships are managed between climate, mitigation policies and sustainable development. Greater integration between studies based on different methodological approaches can show how to construct an enabling environment that increases the feasibility and sustainability of transitions. {17.2, 17.3, 17.4}

Short- and long-term studies of transformations using macroeconomic models and integrated assessment models (IAMs) have identified synergies and trade-offs of mitigation options in the context of development pathways that align sustainable development and climate change (*robust evidence, high agreement*). IAMs often look at climate change mitigation and Sustainable Development Goals (SDGs) in an aggregate manner: supplementing this aggregate view with detail-rich studies involving SDGs can build support for transitions within and across countries (*medium evidence, medium agreement*). {17.3.2}

The impacts of climate change mitigation and adaptation responses, are highly context-specific and scale-dependent. There are synergies and trade-offs between adaptation and mitigation as well as synergies and trade-offs with sustainable development (*robust evidence, high agreement*). A strong link exists between sustainable development, vulnerability and climate risks, as limited economic, social and institutional resources often result in low adaptive capacities and high vulnerability, especially in developing countries. Resource limitations in these countries can similarly weaken the capacity for climate mitigation and adaptation. The move towards climate-resilient societies requires transformational or deep systemic change. This has important implications for countries' sustainable development pathways (*medium evidence, high agreement*). {17.3.3.6}

Sectoral mitigation options present synergies with the SDGs, but there are also trade-offs, which can become barriers to implementation. Such trade-offs are particularly identified in relation to the use of land for bioenergy crops, water and food access, and competition for land between forest or food production (*robust evidence, high agreement*). Many industrial mitigation options, such as efficiency improvements, waste management and the circular economy, have synergies with the SDGs relating to access to food, water and energy (*robust evidence, high agreement*). The promotion of renewable energy in some industrial sectors can imply stranded energy supply investments, which need to

be taken into consideration (*medium evidence, medium agreement*). The agriculture, forestry, and other land uses (AFOLU) sector offers many low-cost mitigation options, but actions aimed at producing bioenergy, extending food access and protecting biodiversity can also create trade-offs between different land uses (*robust evidence, high agreement*). Some options can help to minimise these trade-offs, for example, integrated land management, cross-sectoral policies and efficiency improvements. Lifestyle changes, including dietary changes and reduced food waste, have several synergies with climate mitigation and the SDGs (*medium evidence, medium agreement*). Cross-sectoral policies are important in avoiding trade-offs, to ensure that synergies between mitigation and SDGs are captured, and to ensure local people are involved in the development of new products, as well as production and consumption practices. There can be many synergies in urban areas between mitigation policies and the SDGs, but capturing these depends on the overall planning of urban structures and on local integrated policies, where, for example, affordable housing and spatial planning as a climate mitigation measure are combined with walkable urban areas, green electrification and clean renewable energy. Such integrated options can also reduce the pressures on agricultural land by reducing urban growth, thus improving food security. Access to green electricity can also support quality education (*medium evidence, medium agreement*). {17.3.3, 17.3.3.1, 17.3.3.3}

Digitalisation could facilitate a fast transition to sustainable development and low-emission pathways by contributing to efficiency improvements, cross-sectoral coordination and a circular economy with new IT services and decreasing resource use (*low evidence, medium agreement*). Several synergies with SDGs could emerge in terms of energy, food and water access, health and education, as well as trade-offs, for example, in relation to reduced employment, increasing energy demand and increasing demand for services, all implying increased GHG emissions. However, developing countries with limited internet access and poor infrastructure could be excluded from the benefits of digitalisation (*medium evidence, medium agreement*). {17.3.3}

Actions aligning sustainable development and climate mitigation and partnerships can support transitions. Strengthening different stakeholders' 'response capacities' to mitigate and adapt to a changing climate will be critical for a sustainable transition (*robust evidence, high agreement*). Response capacities can be increased by means of alignment across multiple stakeholders at different levels of decision-making. This alignment will also help achieve synergies and manage trade-offs between climate and sectoral policies by breaking down sectoral silos and overcoming the multiple barriers that prevent transitions from gaining traction and gathering momentum (*medium evidence, high agreement*). {17.1.1.1}

The landscape of transitions to sustainable development is changing rapidly, with multiple transitions already underway. This creates the room to manage these transitions in ways that prioritise the needs for workers in vulnerable sectors (land, energy) to secure their jobs and maintain secure and healthy lifestyles, especially as the risks multiply for those

exposed to heavy industrial jobs and associated outcomes (*medium evidence, high agreement*). A just transition incorporates key principles, such as respect and dignity for vulnerable groups, the creation of decent jobs, social protection, employment rights, fairness in energy access and use, and social dialogue and democratic consultation with the relevant stakeholders, while coping with the effects of asset-stranding and the transition to green and clean economies (*medium evidence, medium agreement*). The economic implications of the transition will be felt especially strongly by developing countries, with high dependence on hydrocarbon products for revenue streams, as they will be exposed to reduced fiscal incomes given a low demand for oil and consequent fall in oil prices (*limited evidence, medium agreement*). {17.3.2, 17.3.2.3}

Countries with assets that are at risk of becoming stranded may lack the relevant resources, knowledge, autonomy or agency to reorientate, or to decide on the speed, scale and quality of the transition (*limited evidence, medium agreement*). The urgency of mitigation might overshadow some of the other priorities related to the transition, like climate change adaptation and its inherent vulnerabilities. Consequently, the transition imperative could reduce the scope and autonomy for local priority-setting and could ignore the additional risks in countries with a low capacity to adapt. A just transition will depend on local contexts, regional priorities, the starting points of different countries in the transition and the speed at which they want to travel. Both mitigation and adaptation warrant urgent and prompt action given current and continuing greenhouse gas (GHG) emissions and associated negative impacts on humanity and ecosystems (*limited evidence, medium agreement*). {17.3.2}

A wide range of factors have been found to enable sustainability transitions, ranging from technological innovations to shifts in markets, and from policies and governance arrangements to shifts in belief systems and market forces (*robust evidence, high agreement*). Many of these factors come together in a co-evolutionary process that has unfolded globally, internationally and locally over several decades (*low evidence, high agreement*). Those same conditions that may serve to impede the transition (i.e., organisational structure, behaviour, technological lock-in) can also 'flip' to enable both it and the framing of sustainable development policies to create a stronger basis and policy support (*robust evidence, high agreement*). It is important to note that strong shocks to these systems, including accelerating climate change impacts, economic crises and political changes, may provide crucial openings for accelerated transitions to sustainable systems. For example, rebuilding more sustainably after an extreme event, or renewed public debate about the drivers of social and economic vulnerability to multiple stressors (*medium evidence, medium agreement*). {17.4}

Sustainable development and deep decarbonisation will involve people and communities being connected through various means, including globally via the internet and digital technologies, in ways that prompt shifts in thinking and behaviour consistent with climate change goals (*medium evidence, medium agreement*). Individuals and organisations

like institutional entrepreneurs can function to build transformative capacity through collective action (*robust evidence, high agreement*), but private-sector entrepreneurs can also play an important role in fostering and accelerating the transitions to sustainable development (*robust evidence, medium agreement*). Ultimately, the adoption of coordinated, multi-sectoral policies targeting new and rapid innovation can help national economies take advantage of widespread decarbonisation. Green industrial policies that focus on building domestic supply chains and capacities can help states prepare for the influx of renewable CDR-methods, or mechanisms for carbon capture and storage (CCS) (*medium evidence, medium agreement*). {17.4.2}

Accelerating the transition to sustainability will be enabled by explicit consideration being given to the principles of justice, equality and fairness. Interventions to promote sustainability transitions that account for local context (including unequal access to resources, capacity and technology) in the development process are necessary but not sufficient in creating a just transition (*low evidence, high agreement*). {17.4.6}

17.1 Introduction

This chapter focuses on the opportunities and challenges for 'accelerating the transition in the context of sustainable development'. The chapter suggests that accelerating transitions in the context of sustainable development requires more than concentrating on speed. Rather, it involves expediting the pace of change (speed) while also removing the underlying drivers of vulnerability and high emissions (quality and depth), and aligning the interests of different communities, regions, sectors, stakeholders and cultures (scale and breadth). One key to enabling deep and broad transitions is integrating the views of different government agencies, businesses and non-governmental organizations (NGOs) in transition processes. Another critical driver of deep and broad transitions is engaging and empowering workers, youth, women, the poor, minorities and marginalised stakeholders in just, equitable and inclusive processes. The result of such processes will be the transformation of large-scale socio-economic systems to restore the health and well-being of the planet and the people on it.

Section 17.1 begins by reviewing how climate and sustainability issues have been discussed in the Intergovernmental Panel on Climate Change (IPCC), as well as international climate change and sustainable development processes at different levels. It further introduces key themes addressed in the chapter's remaining subsections. Section 17.2 provides an overview of how key theories understand transitions and transformation, and notes a shared concern over leveraging synergies and managing trade-offs between climate change and sustainable development across different disciplines. Section 17.3 provides an assessment of the mitigation options that can help achieve these synergies and avoid trade-offs. Section 17.4 pulls together the theoretical and empirical aspects by detailing the essential elements of an enabling environment that helps drive forward transitions that are quick, deep, broad and, ultimately, sustainable.

17.1.1 Integrating Climate Change and Sustainable Development in International Assessments

Climate change not only poses a profound challenge to sustainable development, it is inexorably linked to it. From the early stages of the IPCC assessment process, this challenge and the inherent link between climate change and sustainable development have been well recognised. For example, the First Assessment Report (FAR) highlighted the relevance of sustainable development for climate policy. The Second Assessment Report (SAR) went further to include equity issues in its presentation of sustainable development. The Third Assessment Report (TAR) (Banuri et al. 2001) made the link even stronger, noting that 'parties have a right to and should promote sustainable development' (as stated in the text of the UNFCCC 2015 (Article 3.4)), and offering an early review of studies integrating sustainable development and climate change. The Fourth Assessment Report (AR4) (Sathaye et al. 2007) added an additional perspective to these interconnections, acknowledging the existence of a two-way relationship between sustainable development and climate change.

The Fifth Assessment Report (AR5) (Denton et al. 2014; Fleurbaey et al. 2014) and the Special Report on Global Warming of 1.5°C (SR1.5) (IPCC 2018; Roy et al. 2018a) have arguably made the strongest links between climate and sustainable development to date. One of the key messages of AR5 was that the implementation of climate mitigation and adaptation actions could help promote sustainable development, and it emphasised the need for transformational changes in this regard. The AR5 also concluded that the link between climate change and sustainable development is cross-cutting and complex, and that thus the impacts of climate change are threatening the efforts being made to achieve sustainable development. The SR1.5 helped systematise these links by mapping the synergies and trade-offs between selected SDG indicators and climate mitigation (IPCC 2018; Roy et al. 2018b) (Section 17.3).

Despite the clear links between sustainable development and climate change being recognised from the early stages of the IPCC, climate change has often been portrayed as an environmental problem to be addressed chiefly by environmental ministries (Brown et al. 2007; Munasinghe 2007; Swart and Raes 2007). However, this perception has evolved over time. It is now increasingly common to see governments and other actors understand the wider ramifications of a changing climate for sustainable development. In a growing number of studies, work on climate policies and just transitions towards sustainable development are framed as going hand in hand (Fuso Nerini et al. 2019; Dugarova and Gülasan 2017; Sanchez Rodriguez et al. 2018; Schramade 2017; Zhenmin and Espinosa 2019).

17.1.2 Integrating Climate Change and Sustainable Development in International Policymaking Processes

Among the reasons for the growing realisation of these interdependencies are milestones in international climate and sustainable development processes. As outlined in Chapter 14, the year 2015 was a turning point due to two agreements: (i) the Paris Agreement; and (ii) the 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals (SDGs) (Farzaneh et al. 2021).

Following a long history of references to sustainable development in the UNFCCC and related agreements, the Paris Agreement helped to strengthen the links between climate and sustainable development by emphasising that sustainability is related to its objectives (Sindico 2016; UNFCCC 2016). One of the ways that it helped tighten this link is by institutionalising bottom-up pledges and the review architecture. Toward this end, the Paris Agreement instituted Nationally Determined Contributions (NDCs) as vehicles through which countries make pledges and demonstrate their commitment to climate action. Although there was no clear guidance on what should be included in the NDCs, some of the requirements were elaborated in the Paris Rulebook. Some of the submitted NDCs included only mitigation efforts, but others set out mitigation and adaptation goals aligning NDC commitments to national planning processes, while yet others mentioned links with the SDGs.

Another way that the Paris Agreement and the NDCs could strengthen their links to sustainable development is to update country-specific climate pledges. Countries are free to choose their targets and the means and instruments with which to implement them. A core feature of the NDCs was that countries submit NDCs every five years, giving them an opportunity to assess themselves relative to other countries, raise their ambitions and learn from their peers. Moreover, it was emphasised that countries should not 'backslide' in subsequent NDCs, thus ensuring that countries should always be forward-looking in respect of increasing their ambitions to deliver the Paris Goals. (Höhne et al. 2017) found that, in developing countries especially, the NDC preparation process has improved national climate policymaking.

Despite some favourable reviews, several assessments of specific countries' NDCs (Andries et al. 2017; Rogelj et al. 2016; Vandyck et al. 2016) have assessed that those submitted for 2020–2030 are insufficient for delivering on the Paris goals. Updated and/or new NDCs were therefore submitted by the end of 2020. However, an assessment of those NDCs revealed that the level of ambition was significantly lower than the goals of the Paris Agreement (UNFCCC 2020) (see also this chapter). One of the urgent calls in Paris was to assess the impacts and efforts that need to be undertaken to keep global warming well below 2°C in relation to pre-industrial levels and evaluate related global GHG emission pathways (UNFCCC 2015). Although the initial NDCs fell short of these goals, the idea was that NDCs would be living documents that could ratchet up climate action and ambition.

Countries have also started to take actions on the SDGs themselves (Antwi-Agyei et al. 2018a; UNDESA 2016, 2017, 2018). The SDGs were perceived as a novel approach to development and as establishing a universal agenda for the transformation of development patterns and socio-economic systems. At their core, the SDGs hold that building an integrated framework for action necessitates addressing the economic, social and environmental dimensions of sustainable development in an integrated manner (Biermann et al. 2017; Kanie and Biermann 2017). The SDGs take multiple elements of development into account in aiming to offer coherent, well-integrated, overarching approaches to a range of sustainability challenges, including climate change.

One way a link is made between climate and the SDGs is through Voluntary National Reviews (VNRs). Paralleling the bottom-up orientation of the Paris Agreement and the NDCs, every year approximately forty countries voluntarily share their VNRs with the international community at the High-Level Political Forum (HLPF). Even more flexible than the NDCs, the VNRs can include content such as a summary of key policies and measures that are intended to achieve the SDGs, a list of the means of implementation that support the SDGs, and related challenges and needs. The VNRs also often cover SDG 13 (climate action) as well as many other issues connected with climate change. Even with these links, implementation of the SDGs should be mentioned as part of national development processes reflecting different countries' different priorities, visions and plans (Hanson and Korbla P. Puplampu 2018; Marcotullio et al. 2018; OECD 2016; P. Puplampu et al. 2017; Srikanth 2018).

Yet another way that the 2030 Agenda for Sustainable Development underlines the importance of capturing synergies is its calls for policy coherence (SDGs 14 and 17). Policy coherence and integration between sectors are two of the most critical factors in breaking down the silo mode of working of different sectors. Working across climate and other sustainability agendas is essential to coherence.

A final way that the sustainability and climate agendas have been linked is through vertical integration. Following a similar trend that appeared with Agenda 21, for which many cities adopted local plans, a growing number of cities have introduced Voluntary Local Reviews (VLRs). The VLRs resemble the VNRs, but place the emphasis on local actions and needs regarding the SDGs (and some links to climate change) (Ortíz-Moya et al. 2021). The 2019 SDG Report shows that 150 countries have developed national urban plans, almost half of them also being in the implementation phase (United Nations General Assembly 2019).

17.1.3 Integrating Climate Change and Sustainable Development in Other Policymaking Processes

Other non-UN-led initiatives involving international organisations or clusters of countries have also helped to raise the issue of sustainable development as a framework for mitigation. The OECD, for instance, assesses different types of investments and economic activities with reference to their significance for environmental sustainability (OECD 2020), while G20 countries have drawn up action agendas with sustainable development (UToronto 2016). Meanwhile, the Petersberg Climate Dialogue, a political movement convened by major country-group representatives and launched in 2010 by the German government, has also called for sustainability to be an intrinsic part of the transition (UNFCCC 2020) (BMU 2018).

Due in part to the shifting orientation of these international processes, there is growing evidence of action on climate change and sustainable development at other levels of decision-making. National policies often aim to implement climate change policies in the context of sustainable development (Chimhowu et al. 2019; Chirambo 2018; ECLAC 2017; Fuseini and Kemp 2015; Galli et al. 2018; Haywood et al. 2019; Ministry of Environment of Jordan 2016; McKenzie and Abdulkadri 2018; UNDESA 2016, 2017, 2018; UN Women 2017). Some countries are adjusting their existing policies to build on themes familiar to sustainable development (Lucas et al. 2016), including renewable energy and energy efficiency (Fastenrath and Braun 2018; Kousksou et al. 2015), urban planning (Gorissen et al. 2018; Loorbach et al. 2016; Mendizabal et al. 2018), health systems (Pencheon 2018; Roschnik et al. 2017) and agricultural systems (Lipper and Zilberman 2018; Shaw and Roberts 2017). Cross-cutting and integrated approaches, such as the circular economy, have also been gaining traction in some European countries (EESC 2015) and G20 countries (Noura et al. 2020). Many of these efforts have also extended up to the regional and down to the local level (Gorissen et al. 2018; Hess 2014; Shaw and Roberts 2017).

There has also been a shift to actors outside government aligning climate with sustainable development. An assessment by (Hoyer 2020)

found that collective action against climate change by businesses, governments and civil society, reinforced through partnerships and coalitions across departments, industries and supply chains, can deliver significant development impacts. In order for this diverse collection of stakeholders to take action, a fundamental paradigm shift is needed from a linear model of knowledge-generation to an interdisciplinary model that co-produces knowledge (Liu et al. 2019). In fact, some have argued that accelerating just transitions for purposes of sustainable development requires the involvement of several actors, institutions and disciplines (Delina and Sovacool 2018). Not only do these roles need to be discussed more thoroughly (Kern and Rogge 2016); (den Elzen et al. 2019), but it is also important to survey different views on transitions and transformations. A variety of theories that are useful for explaining the causes and constraints regarding transitions are examined in Section 17.2.

17.2 Accelerating Transitions in the Context of Sustainable Development: Definitions and Theories

This section focuses on how different theoretical frameworks can help us understand and explain what is meant by accelerating transitions in the context of sustainable development. As suggested in Section 17.1, the reference to 'in the context of sustainable development' suggests that sustainable transitions require more than speed, also necessitating removing the underlying drivers of vulnerability and high emissions (quality and depth of transitions), while also aligning the interests of different individuals, communities, sectors, stakeholders and cultures (scale and breadth of transitions).

The outcome of sustainable transitions is a sustainable transformation. While transitions involve 'processes that shift development pathways and reorient energy, transport, urban and other subsystems' (Loorbach et al. 2017) (Chapter 16), transformation is the resulting 'fundamental reorganisation of large-scale socio-economic systems' (Hölscher et al. 2018). Such a fundamental reorganisation often requires dynamic multi-stage transition processes that change everything from public policies and prevailing technologies to individual lifestyles, and social norms to governance arrangements and institutions of political economy. This set of factors can lock-in development pathways and prevent transitions from gathering the momentum needed for transformations. Chapter 16 provides an overview of the multi-stage transition dynamics involved in moving from experimentation to commercialisation to integration to stabilisation. That overview describes how transitions can break through lock-ins and result in a transformation.

While there may be a relatively consistent set of transition dynamics for all countries, pathways are likely to vary across and even within countries. This variation is due to different development levels, starting points, capacities, agencies, geographies, power dynamics, political economies, ecosystems and other contextual factors. Given the diversity of contributing factors, a sustainable transition is likely to be a complex and multi-faceted process which cannot be reduced to a single dimension (Köhler et al. 2019). Even with this multidimensionality, transition processes are likely to gain speed and

become more sustainable as decision-makers adopt targeted policies and other interventions. Many disciplines have reflected on the roles of and relative influence on the policies and interventions that can drive transitions. The following discussion describes this diversity of views with a survey of how prominent lines of economic, psychological, institutional and systems thinking explain transitions. Though these disciplines differ greatly, they often stress that leveraging synergies and managing trade-offs between climate change and sustainable development can help advance a transition.

17.2.1 Economics

This section concentrates on economic explanations for transitions. At the core of many of these explanations is the assumption that economic development can deliver multiple economic, social and environmental benefits. Many modern economic systems may nonetheless struggle to deliver these benefits due to major disruptions and shocks such as climate change (Heal 2020). One way to limit disruptions to free markets are targeted interventions in free markets such as taxes or regulation. These targeted interventions motivate firms and other entities to internalise GHGs and other pollutants, potentially paving the way for a sustainable transition (Arrow et al. 2004; Chichilnisky and Heal 1998).

A related line of thought common to economic explanations involves the principles of 'weak sustainability'. These principles suggest that the substitution of exhaustible resources is, to some extent, feasible (Arrow et al. 2004). One way to capitalise on this substitution is to target investments at technological change, green growth, and research and development. Targeted investments in the form of subsidies can encourage the substitution of exhaustible by non-exhaustible resources. To illustrate with a concrete example, investments in renewable energy can not only mitigate climate change but also offset the use of exhaustible fossil fuels and boost energy security (Heal 2020). It is nonetheless important to note that the principle of 'weak sustainability' contrasts with 'strong sustainability' or 'integrated sustainability' principles. These stronger principles suggest that constraints on resources restrict such substitutions (Rockström et al. 2009). These constraints merit attention because some scarce non-substitutable forms of natural capital can be exhausted (Bateman and Mace 2020). There is hence a need to capitalise on possible synergies such as those with other development priorities and trade-offs, for example, the exhaustion of non-substitutable resources. Capturing these synergies and managing these trade-offs is consistent with sustainable development, a state where the needs of the present generation do not compromise the ability of future generations to meet their own needs (Brundtland, WCED 1987).

As suggested above, aligning climate investments with other sustainable development objectives is critical to a transition. In order to support better investments in sustainable development, financing schemes, including environmental, social and governance (ESG) disclosure schemes and the Task Force on Climate-related Financial Disclosures (TCFD), can play important roles (Executive Summary in Chapter 15 of this report). After COVID-19, economic

recovery packages have increased government-led investments (Section 1.3.3), which could potentially be aligned with sustainable development. Technological change and innovation are considered key drivers of economic growth and of many aspects of social progress (Section 16.1), but if technological innovation policies are coordinated with the shift to sustainable development pathways, then the economic benefits of technological change could come at the cost of increasing climate risks (Gossart 2015) Alarcón and Vos 2015). The environmental impacts of social and economic activities, including emissions of GHGs, are greatly influenced by the rate and direction of technological changes. Innovation and technological transformations present trade-offs that create externalities and rebound effects. This suggests that a sustainable future for people and nature requires rapid, radical and transformative societal change by integrating the technical, governance, financial and societal aspects (Pörtner et al. 2021) (Section 16.1).

One area that is pertinent to transitions and has received considerable attention in economic modelling involving climate change is innovation. In particular, some studies have shown how low-cost innovations and improvements in end-use technologies have significant potential for emissions reductions as well as sustainable development (Wilson et al. 2019). Currently information technologies are improving rapidly, and the internet of things (IoT), AI and Big Data can all contribute to other development needs. This is often the case in end-use sectors, as the benefits accrue directly to the individuals who use the new innovations. The achievement and widespread deployment of fully autonomous cars, for example, will bring about broader car- and ride-sharing with negative or low additional costs compared to more conventional approaches to car ownership, with their typically very low load factors. (Grubler et al. 2018) estimate that the Low Energy Demand (LED) scenario which assumes information technology innovations and induced social changes, including a sharing economy, have considerable potential for harmonising the multiple achievements of SDGs with low marginal abatement costs compared with other scenarios (IPCC 2018).

It is nonetheless important to highlight a caveat to the above logic on innovation. Whether a technological innovation is wholly sustainable or not becomes less clear when considering its effects on the wider economy. To illustrate, some models predict that CO₂ marginal abatement costs in the power sector will be USD240 and USD565 tCO₂ for the 2°C and below 2°C goals, respectively (IEA 2017).

In theory, if marginal abatement costs meet marginal climate damage, mitigation measures are economically optimal in the long run. Yet marginal damage from climate change is notoriously uncertain, and economic theories do not always reflect climate-related damage. On the other hand, marginal abatement mitigation costs impose additional costs in the short term. These added costs can cause productivity in capital to decline through increases in the prices of energy and products in which the energies are embodied. These increased costs can restrict the ability to invest in and achieve the sustainable development priorities. However, precisely the opposite can occur when innovation reduces additional costs or achieves negative costs. If technological innovation leads to the accumulation of capital and productivity increases due to the substitution of

energy, material and labour, these are likely to deliver sustainable development and climate mitigation benefits.

17.2.2 Institutions, Governance and Political Economy

This subsection focuses on institutions, governance and the political economy. Institutional and governance arrangements can influence which actors possess authority, as well as how motivated they are to cooperate in transition processes that are directed at finding solutions to climate change and other sustainability challenges. Often cooperation is enabled when policy frameworks or institutions align climate change with the political and economic interests of national governments, cities or businesses, and when institutional and governance arguments that support that alignment expand the scale of the transitions. However, there may also be political and economic interests and structures that can lock-in unsustainable development patterns, frustrate this alignment and slow down transitions (Haas 2021; Mattioli et al. 2020; Newell and Mulvaney 2013; Power 2016).

An extensive literature has examined how the international climate agreements and architecture influence collaboration across countries regarding climate and sustainable development to support a transition (Bradley 2005). For example, international institutions offer opportunities for governments and other actors to share new perspectives on integrated solutions (Cole 2015). For some observers, however, decades of difficulties in crafting a comprehensive climate change agreement and the resulting fragmented climate policy landscape have been inimical to the collaboration needed for a transition (van Asselt 2014; Nasiritousi and Bäckstrand 2019) (Chapters 1 and 13). Yet others see the potential for more incremental cooperation across countries, even without a single, integrated form of climate governance (Keohane and Victor 2016).

A related argument suggests that fragmentation at the global level provides opportunities for cooperation at the national level (Kanie and Biermann 2017). For example, in contrast to the relatively top-down Kyoto Protocol, the bottom-up pledge and review architecture of the Paris Agreement has prompted national governments to integrate climate change with other sustainable development priorities (Nachmany and SetzerJoana 2018; Townshend et al. 2013). Concrete examples included incorporating the SDGs into the NDCs as an international response to climate change (The Energy and Resources Institute 2017) or bringing climate into sustainable development strategies and so-called Voluntary National Reviews (VNRs) as part of the SDGs and the 2030 Agenda process (Elder and King 2018; Elder and Bartalini 2019).

Another branch of institutional research is concerned with the interactions between multiple levels of governance. In this multi-level governance perspective, cities and other sub-national governments often lead transitions by devising innovative solutions to contribute to climate and local energy, transport, the environment, resilience and other forms of sustainability (Bellinson and Chu 2019; Doll and Puppim De Oliveira 2017; Geels 2011; Koehn 2008; Rabe 2007; van der Heijden et al. 2019). A complementary perspective suggests that national governments can help scale up transitions by allocating

resources and can provide the technical support that can spread innovative solutions (Bowman et al. 2017; Corfee-Morlot et al. 2009; Gordon 2015). Such support has become increasingly important during the pandemic, as national governments transfer funds for investments in climate-friendly infrastructure, transport systems and energy systems. This line of thinking is supported by calls to strengthen vertical and horizontal integration within and across government agencies and stakeholders in ways that can enhance policy coherence (Amanuma et al. 2018; OECD 2018, 2019). The incoherence or misalignment between national and local fiscal institutions and policies can restrict the ability of local governments to secure resources for climate-friendly investments. Such investments are particularly likely to flow, as more local governments have adopted net-zero targets, climate emergency declarations and action plans that can stimulate innovations (Davidson et al. 2020). Others have seen greater potential for collaboration and innovation, with more multi-centred or polycentric forms of governance that lead to the formulation and dissemination of transformative solutions to climate and other environmental challenges (Ostrom 2008). Though much of the above governance research has focused on western countries, there are some applications in other regions and countries such as China (Gu et al. 2020).

Yet another set of channels facilitating integration between climate and other concerns are networks of like-minded actors working across administrative borders and physical boundaries. For instance, city networks such as the Global Covenant of Mayors for Climate & Energy (Covenant of Mayors 2019), the World Mayors Council on Climate Change (ICLEI 2019; C40 Cities 2019) and the United Nations Office for Disaster Risk Reduction (UNDRR 2019) have agreed to share decision-making tools and good practices, and to sponsor ambition-raising campaigns that help align climate and sustainable development concerns within and across cities (Betsill and Bulkeley 2006) (Chapter 8 and Section 17.3.3.5). This can be particularly important for less capable 'following' and 'laggard' cities needing greater financing and other forms of support to move a transition forward (Fuhr et al. 2018).

Furthermore, sub-national governments may often work together with civil-society groups to create new networked forms of governance (Biermann et al. 2012). Other forms of multi-stakeholder partnerships focusing on issues with strong climate synergies, such as forms of air pollution known as short-lived climate pollutants (Climate and Clean Air Coalition (CCAC)) or transport (Sustainable Low Carbon Transport Partnership (SLoCaT)), take their cue from global scientific communities or civic-minded advocacy groups that transmit knowledge across boundaries (Keck and Sikkink 1999). There is also scope for suggesting that the international climate regime serves a Global Framework for Climate Action (GFCA) in helping orchestrate the multilateral climate regime and non-state and sub-national initiatives (Chan and Pauw 2014), though questions remain about its actual impacts on mitigation (Michaelowa and Michaelowa 2017).

Polymaking institutions and networks are themselves policies. A significant literature has looked at integrated policy frameworks and efforts across sectors, including climate adaptation and mitigation, as drivers of transitions (Landauer et al. 2015; Favretto et al. 2018; Obersteiner et al. 2016; Steen and Weaver 2017;

Thornton and Combetti 2017). Policy coherence between climate and other development objectives is often considered essential to sustainable development (Sovacool 2018). A similar discussion about synergies and conflicts has been raised on the relationship between resilience and sustainability (Marchese et al. 2018). To help achieve coherence, there have been some efforts to develop suitable tools and decision-making frameworks (Scobie 2016).

A related line of reasoning has suggested that sustainable development often requires not one but a mix of policy instruments to bring about the multiple policy effects needed for social and technological change (Edmondson et al. 2019; Rogge and Johnstone 2017). Following these calls, some governments have aimed to address climate change and sustainability jointly with coherent and integrated approaches to achieving these agendas (Chimhowu et al. 2019), although for some countries Small Island Developing States (SIDS) this has proven more challenging (Scobie 2016).

Though the above work tends to downplay politics and business, others suggest that political economy should feature prominently in transitions. Some branches of political-economy research underline how resource-intensive and fossil-fuel industries leverage their resources and positions to undermine transitions (Jones, C.A. and Levy 2009; Newell and Paterson 2010; Zhao et al. 2013; Geels 2014; Moe 2014) (Chapter 1). These vested interests can lock-in status quo policies in countries where political systems offer interest groups more opportunities to veto or overturn climate- or eco-friendly proposals (Madden 2014). Companies with a strong interest in earning profits and building competitiveness from conventional fossil fuel-based energy systems have particularly strong incentives to capture politicians and agencies (Meckling and Nahm 2018). Such strategies can be particularly powerful when combined with concerns over job losses and dislocation, preventing transitions from gaining traction (Haas 2021; Mattioli et al. 2020; Newell and Mulvaney 2013; Power 2016).

This suggests that politics can be an impediment to change: other studies argue instead that politics can be harnessed to drive transitions forward. For example, some observers contend that building coalitions around green industrial policies and sequencing reforms to reward industries in such coalitions can align otherwise divergent interests and inject momentum into transitions (Meckling et al. 2015). Others see the effects of political economy varying over time depending upon external market conditions. To illustrate, renewable feed-in tariffs in Europe persisted for over two decades and were crucial in wind and solar power technologies making the breakthrough. But once competition from China led to the demise of European technology providers, and once European populations started to oppose surcharges on their electricity bills, feed-in tariffs were abolished by politicians in the purely national interest (Michaelowa and Michaelowa 2017).

17.2.3 Psychology, Individual Beliefs and Social Change

This subsection draws on value- and action-oriented research that employs inter- or transdisciplinary methods such as transactional

psychology, transformative science and similarly focused disciplines (Wamsler et al. 2021). These approaches frequently encourage researchers to participate in transitions that induce changes in the researcher's own beliefs while triggering wider shifts in social norms (including human stewardship for the natural environment) (Adger et al. 2013; Hulme 2009; Ives et al. 2019; O'Brien 2018). This research also emphasises how changes in individual beliefs could lead to climate actions that contribute to more sustainable, equitable and just societies (e.g., 'the mind- & paradigm shifts') (Göpel et al. 2016). They further suggest the potential for virtuous cycles of individual-level and wider social changes that ultimately benefit the climate (Banks 2007; Day et al. 2014; Lockhart 2011; Montuori and Donnelly 2018; Power 2016).

The starting point for this virtuous circle are inner transitions. Inner transitions occur within individuals, organisations and even larger jurisdictions that alter beliefs and actions involving climate change (Woiwode et al. 2021). An inner transition within an individual (see e.g., Parodi and Tamm 2018) typically involves a person gaining a deepening sense of peace and a willingness to help others, as well as protecting the climate and the planet (see e.g., Banks 2007; Power 2016). Inner transition can imply that individuals become sympathetic to concerns that include climate issues and values connected to nature. For instance, they may include a desire to become a steward of nature (Buijs et al. 2018); 'live according to the principles of integrated sustainability' (Schweizer-Ries 2018); 'achieve the good life' (Asara et al. 2015; Escobar 2015; Kallis 2017; Latouche 2018) (Chapter 5 and Section 1.6.2); or protect the well-being of other living creatures (Chapter 5 and Section 1.6.3.1).

Examples have also been seen in relation to a similar set of inner transitions to individuals, organisations and societies, which involve embracing post-development, degrowth, or non-material values that challenge carbon-intensive lifestyles and development models (D'Alisa 2014; Kothari 2019; Neuteleers and Engelen 2015; Paech 2017). These shifts in values can occur when humans reconnect with nature, deepen their consciousness and take responsibility for protecting the planet and its climate (Cross et al. 2019; Martinez-Juarez et al. 2015; Speldewinde et al. 2015). Changes in both values and beliefs may also emerge through consciousness-raising processes where people cooperate in ways that would protect the climate ((Banks 2007; Hedlund-de Witt et al. 2014; Woiwode and Woiwode 2019) (Section 1.6.4).

Many of the above-mentioned beliefs and values that support climate actions have spread through expanding interests in conservationist world views, indigenous cultures (see, for example, Lockhart 2011) and branches of neuroscience and psychology that suggest different notions of the self (Hüther 2018; Lewis 2016; Seligman and Csikszentmihalyi 2014). These beliefs and values can also be spread through meditation, yoga or other social practices that encourage lower-carbon lifestyles (Woiwode and Woiwode 2019). Another channel for spreading climate concerns is sustainability culture, which is premised on connecting people and communities, and has also benefited from the internet and digital technologies that support these connections (see e.g., Bradbury 2015; Scharmer 2018). The spread of this culture, in turn, has led

to the creation of social fields that allow changes to happen (see e.g., Gillard et al. 2016) or has promoted low-carbon thinking and related behavioural changes (O'Brien 2018; Veciana and Ottmar 2018). Studies of social contagions may also offer insights into the mechanisms that lead to the adoption of new values and related climate actions (see e.g., Iacopini et al. 2019). It is nonetheless worth highlighting that communication networks and other mechanisms promoting the spread of interpersonal communication that can spread pro-climate views may also lead to the proliferation of climate scepticism and denial (Leombruni 2015). At the same time, some studies suggest that such scepticism can be countered by the generation of more credible information on climate change (Samantray and Pin 2019).

One of the more direct channels through which transitions spread are climate change education and action-oriented research (Fazey et al. 2018; Ives et al. 2019; Scharmer 2018; Schäpke et al. 2018; Schneidewind et al. 2016). For instance, research using 'social experiments' or 'real-world labs' has helped give rise to shifts in mindsets on energy, food, transport and other systems that can benefit the climate (Bernstein and Hoffmann 2018; Berkhout et al. 2010; Bulkeley et al. 2015; Hoffmann 2010). In much the same way, the acquisition of transformational knowledge and transformative learning (Lange 2018; O'Neil and Boyce 2018; Pomeroy and Oliver 2018; Walsh et al. 2020; Williams 2013) contributes to thinking and acting that open climate-friendly development pathways (Berkhout et al. 2010; Lo and Castán Broto 2019; Roberts et al. 2018; Turnheim and Nykvist 2019)) (Section 1.7.2). First-person and action research can also facilitate similar changes that bring about climate actions (see e.g., Dick 2007; Streck 2007; Hutchison and Walton 2015; Bradbury et al. 2019).

17.2.4 System-level Explanations

Systems explanations help explain the dynamics of transitions toward sustainable development while explicitly uncovering links between the human and natural worlds, the socio-cultural embeddedness of technology, and the inertia behind high-carbon development pathways. This line of thinking often envisages transitions emerging from complex systems in which many different elements interact at small scales and spontaneously self-organise to produce behaviour that is unexpected, unmanaged and fundamentally different from the sum of the system's constituent parts.

Social-ecological systems theory describes the processes of exchange and interaction between human and ecological systems, investigating in particular non-linear feedback occurring across different scales (Folke 2006; Holling 2001). This approach has informed subsequent theoretical and empirical developments, including the 'planetary boundaries' approach (Rockström et al. 2009), conceptualisations of vulnerability and adaptive capacity (Hinkel 2011; Pelling 2010) and more recent explorations of urban resilience (Romero-Lankao et al. 2016) and regenerative sustainability (Clayton and Radcliffe 2018; Robinson and Cole 2015). Employing a systems lens to address the 'root causes' of unsustainable development pathways (such as dysfunctional social

or economic arrangements) rather than the 'symptoms' (dwelling quality, vehicle efficiency, etc.) can trigger the non-linear change needed for a transformation to take place (Pelling et al. 2015). Exploring synergies between climate change adaptation, mitigation and other sustainability priorities (such as biodiversity and social equity, for instance) (Beg 2002; Burch et al. 2014; Shaw et al. 2014) may help to yield these transformative outcomes, though data regarding the specific nature of these synergies is still emerging.

Socio-technical transition theory, on the other hand, explores the ways in which technologies such as low-carbon vehicles or regenerative buildings are bound up in a web of social practices, physical infrastructure, market rules, regulations, norms and habits (see, e.g., (Loorbach et al. 2017)). Radical social and technical innovations can emerge that ultimately challenge destabilised or increasingly ineffective and undesirable incumbents, but path dependencies often stymie these transition processes, suggesting an important role for governance actors (Burch 2017; Frantzeskaki et al. 2012; Holscher et al. 2019).

This also reveals the large-scale macroeconomic, political and cultural trends (or contexts) that may reinforce or call into question the usefulness of current systems of production and consumption. One branch of this theory, transition management (Kern and Smith 2008; Loorbach 2010), explores ways of guiding a socio-technical system from one path to another. In particular, it highlights interactions between actors, technologies and institutions, and the complex governance mechanisms that facilitate them (Smith et al. 2005). The challenge, in part, becomes linking radical short-term innovations with longer-term visions of sustainability (Loorbach and Rotmans 2010) and creating opportunities for collaborative course-correction in light of new information or unexpected outcomes (Burch 2017).

17.2.5 Conclusions

This section has surveyed several explanations for interventions that can give rise to transitions. The review suggests that there are several differences between these various perspectives. Whether individuals, organisations, markets or socio-technical systems drive or undermine transitions is a key distinction. These differences have implications for the evidence these claims draw on in support of their arguments. For instance, some of the explanations tend to employ qualitative evidence to explain changes in attitudes at the individual or community levels as paving the way for broader changes to cultures and belief systems. Others assess how institutional arrangements can be reformed in order to align climate with the sustainable development agenda to enable a transition.

While there are indeed significant differences between explanations, there are also important parallels. Such parallels begin with a shared emphasis on synergies and trade-offs between climate and sustainable development. Most explanations tend to underline the importance of synergies in aligning the climate with broader sustainability agendas. Most importantly, many of the explanations are complementary with the systems-level discussion in that they offer a broad framework,

while economic, psychological and governance theories offer more specific insights. Moving a transition forward will often require drawing upon insights from multiple schools of thought. Though it is unlikely that a one-size-fits-all set of factors will drive a transition, there is a growing body of empirical evidence shedding light on the factors that can strengthen synergies between climate and the broader sustainable development agenda.

17.3 Assessment of the Results of Studies Where Decarbonisation Transitions are Framed Within the Context of Sustainable Development

17.3.1 Introduction

This section assesses studies based on the links between sustainable development and climate change mitigation in order to facilitate robust conclusions on synergies and trade-offs between different policy objectives across methodologies, scenarios and sectors. Conclusions are drawn based on national and sub-national, sectoral and cross-sectoral, short- and long-term transition studies presented in this and other sections of the report as a basis for establishing an overall picture of how sustainable development and climate change policies can be linked as a basis for accelerated transitions.

This section focuses initially on issues related to short- and long-term transitions to meet climate change and sustainable development goals in the context of the UNFCCC and the UN 2030 Agenda for Sustainable Development. Global-modelling results and economy-wide studies are then assessed, followed by a discussion of specific challenges in relation to renewable-energy penetration and phasing out fossil fuels, stranded assets and just transitions. Key synergies and trade-offs between meeting the UN 2030 Sustainable Development Goals (SDGs) and mitigation are then illustrated by means of cross-sectoral examples. Finally, this section presents an overview of the assessment of SDG synergies and trade-offs based on all sectoral chapters in this report for a range of key mitigation options.

17.3.2 Short-term and Long-term Transitions

It is increasingly being recognised that sustainable development policy goals and meeting short- and long-term climate policy goals are closely linked (IPCC 2018). It is also being realised that, under the Paris Agreement, climate change policies should be integrated into sustainable development agendas, while the UN 2030 Agenda as well includes SDG 13 on climate actions. In this way, both UN agreements provide joint opportunities for systematic transitions in support of both climate change and sustainable development. Achievement of the Paris Agreement's goals will require a rapid and deep worldwide transition in all GHG emissions sectors, including land use, energy, industry, buildings, transport and cities, as well as in consumption and behaviour (UNEP 2019). Meeting the goals of such a transformation requires that the long-term targets and pathways to fulfil the stabilisation scenarios play an important role in guiding the direction and pathways of short-term transitions. There is therefore

a need for long- and short-term policies and investment decisions to be closely coordinated.

In the context of the Paris Agreement, countries have submitted their initial plans for the decarbonisation of their economies to the UNFCCC in the form of their so-called National Determined Contributions (NDCs). The ambitions of the NDCs are closely related to the ongoing UNFCCC negotiations over the financial measures and forms of compensation. Although the Paris Agreement emphasises the links between climate policies and sustainable development, the UN's 2030 Agenda for Sustainable Development and the SDGs are not very well represented at present in the NDCs, according to Fuso Nerini et al. (2019). Very few of the NDCs include any reference to the SDGs, which (Fuso Nerini et al. 2019) highlight as a barrier to the successful implementation of the Paris Agreement, which induces them to call for a more holistic policy approach. Campagnolo and Davide (2019) have assessed the impacts of the submitted NDCs on poverty eradication and inequalities of income based on empirical research and a global Computable General Equilibrium (CGE) model. One conclusion is that the NDCs of less developed countries would tend to reduce poverty alleviation, but this can be offset if international financial support is provided for the mitigation actions.

The alignment of climate-policy targets in the NDCs with sustainable development has been assessed by means of integrated assessment models (IAMs), macroeconomic and sectoral modelling. (Iyer et al. 2018) based on IAM-based studies, the implications of framing NDCs being placed more narrowly on mitigation targets rather than on a framing in which the impacts on sustainable development were explicitly taken into consideration. It was thus concluded that some SDGs would be directly supported as a side benefit of the climate policy targets included in the NDCs, while other SDGs needed a special policy design going beyond narrow climate policy objectives. (Iyer et al. 2018) also assessed the regional distribution of efforts in terms of domestic mitigation costs and SDG impacts and concluded that the geographical distribution of mitigation costs and SDG benefits were not similar, so a special effort would be needed to match climate policies and policies to meet the SDGs. Accordingly, a national decision-making perspective suggests that SDGs should be integrated into national climate policies.

The NDCs submitted to the Paris Agreement have demonstrated a lack of progress in meeting the long-term temperature goals. In the context of the UN's 2030 Agenda for Sustainable Development, the UN Sustainable Development Report 2019 (Sachs et al. 2019) also concluded that there is a particular lack of progress in achieving SDG 13 (climate action), SDG 14 (life below water) and SDG 15 (life on land). Given the close link between the SDGs and climate change policies, the current obstacles in meeting the former could also be a barrier to realising transitions to low-carbon societies. Conversely, opportunities to leverage the SDGs could in many cases involve climate actions, since policies enabling climate adaptation and mitigation could also support food and energy security and water conservation if they were well designed (see the detailed discussion in the section on synergies and trade-offs between climate policies and meeting the SDGs in Section 17.3.3.7, Chapter 3, and IPCC 2018). These findings point to a specific need to align economic and social

development perspectives, climate change and natural systems. While all countries share the totality of the SDGs, development priorities differ across countries and over time. These priorities are strongly linked to local contexts and depend on which dimension of the improvement in the well-being of people is considered to be the most urgent. Eradicating poverty and reducing inequality are key development priorities for many low- and middle-income countries (Section 4.3.2.1).

A key barrier to the development of national plans and policies to meet the UN 2030 SDGs is the lack of finance. (Sachs et al. 2019) conclude that meeting the SDGs to achieve social transformations worldwide would require 2–3% of global GDP and that it would be a huge challenge to ensure that finance is targeted to the world's poorest countries and people. The UN Secretary-General has called for the allocation of finance to meet the UN's 2030 Agenda with a strong emphasis on the private sector, but to date no governance frameworks or associated financial modalities have been established in the UN or the UNFCCC context for the formal alignment of sustainable development and transitions to take place in accordance with the low global temperature-stabilisation targets in the Paris Agreement. Accelerating investments, particularly in low-income countries, will be required to meet both the Paris goals and the SDGs (Section 15.6.7). The mismatch between capital and investment needs, home-bias considerations and differences in risk perceptions between rich and poor represent major challenges for private finance. Green bond markets and markets for sustainable financial products have increased significantly, and the landscape has continued to evolve since AR5 (Executive Summary in Chapter 15). Special efforts and activities are particularly required for raising finance in developing countries.

Based on the Paris Agreement, the UNFCCC has invited countries to communicate their mid-century and long-term low-GHG emission-development strategies by 2020 (UNFCCC 2019). National long-term low-emission development strategies and their global stocktake in the UNFCCC context provide a platform for informing the long-term strategic thinking on transitions towards low-carbon societies. One specific value of these plans is that they reflect how specific transition pathways, policies and measures can work in different parts of the world in a very context-specific way, that is, by taking context-specific issues and stakeholder perspectives into consideration. Many nations have submitted national long-term strategies to the UNFCCC, including sustainable development perspectives (see Section 4.2.4 for a review of the plans and scientific assessments).

17.3.2.1 Model Assessments on the Sustainable Development Pathways for Decarbonisation

This section assesses the model evaluations of the sustainable development pathways for decarbonisation, including the co-benefits and trade-offs involving explorations of alternative future development pathways as a basis for clarifying societal objectives and understanding the restrictions. Shifting development pathways to increased sustainability involves a number of complex issues, which are difficult to integrate into models. For a more detailed discussion about this, see Section 4.4.1 and Cross-Chapter Box 5 in Chapter 4.

Development pathways that focus narrowly on climate mitigation or economic growth will not lead to the SDGs and long-term climate-stabilisation objectives being achieved. The best chances of doing this lie in development pathways that can maximise the synergies between climate mitigation and sustainable development more broadly (Section 1.3.2). Areas of focal modelling include green investments, technological change, employment generation and the performance of policy instruments, such as green taxes, subsidies, emission permits, investments and finance. Short- and long-term macroeconomic models have been used to assess the impacts of such policy instruments. Jaumotte et al. (2021) analyse the economic impacts on net zero emissions by 2050 with a focus on short-term economic policies and the integration of climate policies such as CO₂ taxes with green reform policies. This may imply the co-creation of benefits between climate policy objectives, and macroeconomic policy goals such as employment creation.

There is an emerging modelling literature focusing on the synergies and trade-offs between low-carbon development pathways and various aspects of sustainable development. The early literature, including that on IAMs, and macroeconomic and sectoral models, mainly focused on the co-benefits of mitigation policies in terms of reduced air pollution, energy security and to some extent employment generation security (IPCC 2014, 2018c) (Chapter 6). Some models have been developed further with assessments of a broader range of the joint benefits of mitigation, health, water, land use and food security (Clarke et al. 2014; IPCC 2014, 2018; Kolstad et al. 2014). According to Chapter 1, there is a need to incorporate issues and enablers further, including a wide range of non-climate risks, varying forms of innovation, possibilities for behavioural and social change, feasible policies and equity issues (Executive Summary in Chapter 1).

IAMs and macroeconomic models typically calculate mitigation costs based on the assumption that markets internalise externalities like GHG emissions through carbon prices (Barker et al. 2016; IEA 2017, 2019). Yet, there are legitimate questions to be asked about whether carbon pricing will be efficient if markets are inefficient (World Bank 2019). However, market inefficiencies are difficult to integrate into the models. How GHG emissions taxes would actually work is thus quite uncertain based on the modelling studies (Barker et al. 2016; Fontana and Sawyer 2016; Meyer et al. 2018). Despite these limitations, the use of GHG emission taxes as an effective instrument based on modelling results in practice has implications for public policies and private-sector investments.

Despite the shortcomings of conventional economic thought and models already pointed out, improved models have demonstrated new perspectives on how mitigation costs can be assessed in macroeconomic models. For instance, while a conventional perspective might suggest that climate change mitigation costs can limit investments in sustainability because they reduce the productivity of capital by increasing energy prices and the products in which energies are embodied, another perspective is that innovation can imply increases in efficiency and that the substitution of energy, material and labour can lead to the accumulation of capital and productivity gains. This appears to occur with innovations in end-use energy applications generating emissions reductions and delivering

on other sustainable development benefits (Wilson et al. 2019). Similarly, IAM models have been applied to model the potential for Low Energy Demand (LED) scenarios associated with demand-side innovations in the service sector. (Grubler et al. 2018) have developed a climate-friendly LED scenario which assumes information technology innovations such as the internet of things (IoT) and induced social changes such as the sharing economy. Nonetheless there are still very important limits on the degree to which highly aggregated IAM models and macroeconomic models can integrate ethics, equity and several other key policy-relevant aspects of sustainable development (Easterlin et al. 2010; Koch 2020). A key limitation in this context is that, while all countries share the totality of the SDGs, development priorities differ across countries and over time. Moreover, these priorities are strongly linked to local contexts, and this can only be reflected directly in national models (Section 4.3.2).

An example of a project that assesses the economy-wide impacts of linking sustainable development with deep decarbonisation is the Deep Decarbonisation Pathways Project (DDPP) (Bataille et al. 2016), which is undertaking a comparative assessment of studies of 16 countries representing more than 74% of global energy-related emissions for the pathway to 2°C stabilisation scenarios. The DDPP's methodology is to combine scenario analysis in different national contexts using macroeconomic models and sectoral models and to facilitate a consistent cross-country analysis using a set of common assumptions.

The key conclusions of the DDPP team on the economy-wide impacts are that country-based studies such as South Africa's demonstrate that it is possible to improve income distribution, alleviate poverty and reduce unemployment while simultaneously transitioning to a low-carbon economy (Altieri et al. 2016). The DDPP in Japan explores whether energy security can be enhanced through increases in renewable energy (Oshiro et al. 2016). The reduction of uncontrolled fossil fuel emissions has significant public-health benefits according to the Chinese and Indian DDPPs, as fossil fuel combustion is the major source of air pollution.

For example, in the Chinese DDPP, deep decarbonisation scenarios have resulted in reductions of 42–79% in primary air pollutants (e.g., SO₂, NO_x, particulate matter (PM_{2.5}), volatile organic compounds (VOCs), and NH₃), thus meeting air-quality standards in major cities. The deep decarbonisation scenarios include the large and fast energy-efficient improvements required to improve energy access and affordability. The DDPP studies are thus an example of an approach in which national deep-carbonisation scenarios are linked to the development goals of income generation, energy access and affordability, employment, health and environmental policy.

Sustainable development scenarios have also been developed by the Low-Carbon Society's (LCS) assessments (Kainuma et al. 2012), in which multiple sustainable development and climate change mitigation goals were assessed jointly. The scenario analysis was conducted for Asian countries such as South Korea, Japan, India, China and Nepal with a soft linked IAM using economy-wide and sectoral models and linked to very active stakeholder engagement in order to reflect national policy perspectives and priorities. Some of

the models are economy-wide global IAMs, while others are national partial equilibrium models.

The LCS scenarios also include a specific attempt to include ongoing dialogues with policymakers and stakeholders in order to reflect governance and enabling factors, and to enable the modelling processes to reflect political realism as far as possible. Diverse stakeholders who acted as validators of the scientific process were included, stakeholder preferences were revealed, and recipients and users of the LCS outputs were included in ongoing dialogues on outputs and in interpreting the results. The aim of the stakeholder interactions was thus to fill the gap between typical laboratory-style IAMs and down-scaled but unaligned practical assessments performed at disaggregated geographical and sector-specific scales.

Energy scenarios for sustainable development were included in The World Energy Outlook of the IEA (IEA 2019, 2020) in terms of a Sustainable Development Scenario (SDS), which assessed not only SDG 13 (climate action) but also SDG 7 (affordable and clean energy) and SDG 3.9 (air pollution). This scenario takes as its starting point the policy goal of meeting these SDGs and then assesses the costs of meeting an emissions reduction target of 70% of CO₂ from the energy system by 2030. The scenario concludes that retrofitting coal-fired power plants with pollution controls is the cheapest option for dealing with local pollution in the short term, but that this is not consistent with meeting the long-term emissions goals of the Paris Agreement. The SDS scenario combines the goal of reducing the amount of CO₂ in the energy system by 70%, with large decreases in energy-related emissions of NO_x, SO₂ and PM_{2.5}, leading to a fall of 40–60% by 2030, and to 2.5 million fewer premature deaths from air pollution in 2030 than in the Stated Policies Scenario (STEPS), which represent a continuation of current trends in the energy system (IEA 2020).

The costs of energy-system transitions have been assessed by several energy-system studies. The economic costs of meeting the different goals depend on the stringency of the mitigation target, as well as economic (fuel prices, etc.) and technological developments (technology availability, capital costs, etc.). In addition, changes in infrastructure and behavioural patterns and lifestyles matter. Model-based assessments vary, depending on these assumptions and differences in modelling approaches (Krey et al. 2019) (Section 6.7.7). Country characteristics determine the social, economic and technical priorities for low-emission pathways. Domestic policy circumstances impact on pathways and costs, for example, when affordability and energy-security concerns are emphasised (Oshiro et al. 2016).

Mitigation policies can have important distributive effects between and within countries, and may affect impact on the poorest through their effects on energy and food prices (Hasegawa et al. 2018; Fujimori et al. 2019) (Section 3.6.4), while higher levels of warming are projected to generate higher inequality between countries as well as within them (Chapter 16). Mitigation thus can reduce economic inequalities and poverty by avoiding such impacts (Section 3.6.4).

Improved air quality and the associated health effects are the co-benefit category dominating model-based assessments of

co-benefits, but a few studies have also covered other aspects, such as the health effects of dietary change and biodiversity impacts (Sections 3.6.3 and 17.3). Mitigation has implications for global economic inequalities through different channels and can compound or lessen inequalities, avoid impacts and create co-benefits that reduce inequalities (Section 3.6.4). There are, however, several challenges involved in balancing the dilemmas associated with meeting the SDGs, such as, for example, energy access, equity and sustainability. Fossil fuel-dependent developing countries cannot transition to low-carbon economics without considering the wider impacts on development by doing so (Section 3.7.3).

Climate change has negative impacts on agricultural productivity in general, including unequal geographical distribution (Chapter 3). On top of that, there is also a risk that climate change mitigation aimed at achieving stringent climate goals could negatively affect food access and food security (Akimoto et al. 2012; Fujimori et al. 2019; Hasegawa et al. 2018). If not managed properly, the risk of hunger due to climate policies such as large-scale bioenergy production increases remarkably if the 2°C and 1.5°C targets are implemented (Section 3.7.1). Taking the highest median values from different IAMs for given classes of scenarios, up to 14.9 GtCO₂ yr⁻¹ carbon dioxide removal (CDR) from BECCS is required in 2100, and 2.4 GtCO₂ yr⁻¹ for afforestation. Across the different scenarios, median changes in global forest area throughout the 21st century reach the required 7.2 Mkm² increases between 2010 and 2100, and agricultural land used for second-generation bioenergy crop production may require up to 6.6 Mkm² in 2100, increasing the competition for land and potentially affecting sustainable development (AR6 scenarios database).

Reducing climate change can reduce the share of the global population exposed to increased stress from reductions in water resources (Arnell and Lloyd-Hughes 2014) and therefore to water scarcity as defined by a cumulative abstraction-to-demand ratio (Hanasaki et al. 2013). (Byers et al. 2018), show that 8–14% of the population will be exposed to severe reductions in water supply if average temperatures increase between 1.5°C and 2°C (Section 3.7.2). (Hayashi et al. 2018) assess the water availability for different emission pathways, including the 2°C and 1.5°C targets, in light of the various factors governing availability. There are very different impacts among nations. In Afghanistan, Pakistan and South Africa, water stress is estimated to increase by 2050 mainly due to increases in irrigation water associated with the rising demand for food, and climate change will already increase water stress within the next decades. Other factors, such as changes in the demand for municipal water, water for electricity generation, other industrial water, and water for livestock due to climate change mitigation, are of limited importance.

(Vandyck et al. 2018) estimate that the 2°C pathway would reduce air pollution and avoid 0.7–1.5 million premature deaths in 2050 compared to current levels. It is generally agreed that in both developed and developing countries there are additional benefits of climate change mitigation in terms of improved air quality (Section 3.7.4). (Markandya et al. 2018) assessed the health co-benefits of air pollution reductions and the mitigation costs of the Paris Agreement using global scenarios for up to 2050. They

concluded that the health co-benefits substantially outweighed the policy costs of achieving the NDC targets and either 2°C or 1.5°C stabilisation. The ratio of health co-benefits to the mitigation costs ranged from 1.4 to 2.45, depending on the scenario. The extra effort of trying to pursue the 1.5°C target instead of the 2°C target would generate a substantial net benefit in some areas. In India, the co-health benefits were valued at USD3.28–8.4 trillion and those in China at USD0.27–2.31 trillion. (Gi et al. 2019) also show that developing countries such as India have a huge potential to produce co-benefits. In addition, this implies that while the cost advantages of simultaneously achieving reductions of CO₂ emissions and of PM_{2.5} are clear, the advantages for integrated measures could be limited, as the costs greatly depend on the CO₂ emissions reduction target.

(Grubler et al. 2018) models a pathway leading to global temperature change of less than 1.5°C without carbon capture and storage (CCS), taking end-use changes into account, including innovations in information technologies and changes to consumer behaviour apart from passive consumption. The pathway estimates global final-energy demand of 245 EJ yr⁻¹ in 2050, which is much lower than in existing studies (Section 5.3.3). It also shows the possibilities of creating synergies between multiple SDGs, including hunger, health, energy access and land use. Integrated technological and social innovations will increase the opportunity to achieve sustainable development. (Millward-Hopkins et al. 2020) estimate global final energy at 149 EJ yr⁻¹ in 2050 as required to provide decent material living standards, which is much lower than the 1.5°C scenario ranges (330–480 EJ yr⁻¹ in 2050) of IAMs (IPCC 2018) and the 390 EJ yr⁻¹ in the IEA SDS (IEA 2019), and also lower than (Grubler et al. 2018). The conclusion is that, although providing material living standards does not guarantee that every person will live a good life, there are large potentials in achieving low energy demand with sustainable development.

An overview of the co-benefits and trade-offs of several SDGs based on modelling results is provided in Figure 3.39 (Section 3.7). Selected mitigation co-benefits and trade-offs are provided in relation to meeting the 1.5°C temperature goal based on a subset of models and scenarios, despite many IAMs so far not having comprehensive coverage of the Sustainable Development Goals (Rao et al. 2017; van Soest et al. 2019). There are several co-benefits of mitigation policies, including increased forest cover (SDG 15) and reduced mortality from ambient PM_{2.5} pollution (SDG 3) compared to reference scenarios. However, mitigation policies can also cause higher food prices and thus increase the share of the global population at risk from hunger (SDG 2), while also relying on solid fuels (SDGs 7 and 3) as side effects. It is then concluded in Section 3.7 that these trade-offs can be balanced through targeted support measures and/or additional SD policies (Bertram et al. 2018; Cameron et al. 2016; Fujimori et al. 2019).

The World in 2050 Initiative (TWI2050) includes a comprehensive assessment of technologies, economies and societies embodied in the SDGs (IIASA 2018). The assessment addresses social dynamics, governance and sustainable development pathways within the areas of human capacity and demography, consumption and production, decarbonisation and energy, food, the biosphere and water, smart cities and digitalisation. The report concludes that the 17 SDGs are integrated and complementary and need to be addressed in

unison. Studies using global IAMs that were presented in the GEO6 report (United Nations Environment Programme 2019, Chapter 22) concluded that transitions to low-carbon pathways will require a broad portfolio of measures, including a mixture of technological improvements, lifestyle changes and localised solutions. The many different challenges require dedicated measures to improve access to, for example, food, water and energy, while at the same time reducing the pressure on environmental resources and ecosystems. A key contribution may be a redistribution of access to resources, where both physical access and affordability play a role. The IAMs cover large countries and regions, and localised solutions are not properly addressed in the modelling results. This implies that, for example, trade-offs between energy access and affordability are not fully represented in aggregate modelling results.

There are also several country-level studies for deep emissions reductions (see Chapter 4 for an overview of the results). The studies find significant impacts of mitigation policies at the sectoral level, reflecting the fact that the sectoral scope does not allow for as much flexibility in mitigation measures despite macroeconomic impacts being assessed to be small (Executive Summary in Chapter 4). Another key lesson is that the detailed design of mitigation policies is critical for the distributional impacts (Executive Summary in Chapter 4). The potential mitigation measures, the potential economic growth, the political priorities and so forth are different among nations, and there may be several emissions-reduction transition pathways to long-term goals among nations (Figure 4.2).

17.3.2.2 Renewable Energy Penetration and Fossil Fuel Phase-out

As pointed out in Chapter 6, the achievement of long-term temperature goals in line with the Paris Agreement requires the rapid penetration of renewable energy and a timely phasing out of fossil fuels, especially coal, from the global energy system. Limiting warming to 1.5°C (>50%) with no or limited overshoot means that global CO₂ emissions must reach 'net zero' in 2050/2060 (IPCC 2018). Net zero emissions imply that fossil fuel use is minimised and replaced by renewables and other low-carbon primary forms of energy, or that the residual emissions from fossil fuels are offset by carbon dioxide removal (CDR). The 1.5°C scenario requires a 2–3% annual improvement rate in carbon intensities till 2050. The historical record only shows a slight improvement in the carbon intensity rate of global energy supplies, far from what is required to limit global warming to 2°C (>67%), or limit warming to 1.5°C (>50%) with no or limited overshoot.

The role of coal in the global energy system is changing fast. Given the global temperature goals of the Paris Agreement, the global coal sector needs a transition to near zero by 2050 – earlier in some regions (Bauer et al. 2018; IEA 2017; IPCC 2018). Other global trends, including air quality, water shortages, the improved cost efficiencies of renewables, the technical availability of energy storage and the economic rebalancing of emerging countries, are also driving global coal consumption to a plateau followed by a reverse (Sator 2018; Spencer et al. 2018). The world should be prepared for a managed transition away from coal and should identify appropriate transition

options for the future of coal, which can include both the penetration of renewable energy and improvements in energy efficiency (Shah et al. 2015).

Phasing out fossil fuels from energy systems is technically possible and is estimated to be relatively low in cost (Chapter 6). The cost of low-carbon alternatives, including onshore and offshore wind, solar photovoltaic (PV) and electric vehicles, has been reduced substantially in recent years and has become competitive with fossil fuels (Shen et al. 2020). However, studies show that replacing fossil fuels with renewables can have major synergies and trade-offs with a broader agenda of sustainable development (Swain and Karimu 2020), including land use and food security (McCollum et al. 2018), decent jobs and economic growth (Swain and Karimu 2020). Clarke et al. (AR5 WG III Table 6.7) provides detailed mapping of the sectoral co-benefits and adverse side-impacts of and links to transformation pathways. In Section 17.3.3.7, this is supplemented with a mapping of the synergies and trade-offs between the deployment of renewable energy and the SDGs.

The general conclusion is that the potential co-benefits of renewable-energy end-use measures outweigh the adverse impacts in most sectors and in relation to the SDGs, though this is not the case for the AFOLU (agriculture, forestry and other land use) sectors. Some locally negative economic impacts can result in increased energy costs and competition over land areas and water resources. Some sectors may also experience increasing unemployment as a consequence of the transition process. Although the deployment of renewable energy will generate a new industry and associated jobs and benefits in

some areas and economies, these impacts will often not directly replace or offset activities in areas that have been heavily dependent on the fossil fuel industry.

The transition to low-emission pathways will require policy efforts that also address the emissions that are locked-in to existing infrastructure such as power plants, factories, cargo ships and other infrastructure already in use: for example, today coal-fired power plants account for 30% of all energy-related emissions (IEA 2019). Over the past twenty years, Asia has accounted for 90% of all coal-fired capacity built worldwide, and these plants have potentially long operational lifetimes ahead of them. In developing economies in Asia, existing coal-fired plants are just twelve years old on average. There are three options for bringing down emissions from the existing stock of plants: to retrofit them with carbon capture and storage (CCS) or biomass co-firing equipment; to repurpose them to focus on providing system adequacy and flexibility while reducing operations; and to retire them early. In the IEA Sustainable Development Scenario, most of the 2080 GW of existing coal-fired capacity would be affected by one of these three options.

Even though the transition away from fossil fuels is desirable and technically feasible, it is still largely constrained by existing fossil fuel-based infrastructure and stranded investments. The 'committed' emissions from existing fossil fuel infrastructure may consume all the remaining carbon budget in the 1.5°C scenario, or two thirds of the carbon budget in the 2°C scenario (Tong et al. 2019). (Kefford et al. 2018) assess the early retirement of fossil fuel power plants in the US, EU, China and India based on the IEA 2°C scenario and

Box 17.1 | Case Study: Coal Transitions

The coal transition will pose challenges not only to the power sector, but even more importantly to coal mining. A less diversified local economy, low labour mobility and heavy dependence on coal revenues will make closing down coal production particularly challenging from a political economy perspective. Policy is needed to support and invest in impacted areas to smooth the transition, absorb the impact and incentivise new opportunities. A supportive policy for the transition could include both short-term support and long-term investment. Short-term compensation could be helpful for local workers, communities, companies and governments to manage the consequences of coal closures. Earlier involvement with local stakeholders using a structured approach is crucial and will make the transition policy more targeted and better administered. The long-term policy should target support to the local economy and workers to move beyond coal, including a strategic plan to transform the impacted area, investment in local infrastructure and education, and preference policies to incentivise emerging businesses. Most importantly, *ex ante* policy implementation is far better than *ex post* compensation. Even without the climate imperative, historical evidence shows that coal closures can happen surprisingly fast.

Presently, coal-fired power plants play a key role in the German energy system, providing almost 46% of the electricity consumed in Germany. These coal power plants play a crucial role in balancing fluctuations in producing electricity from renewables (Parra et al. 2019). Political and economic considerations, at least regionally, are also of great importance in the coal sector due to the approximately 35,000 people employed within it (including coal mining and the power stations themselves). For a long time, coal-fired power plants were able to protect their position in Germany, but against the background of decreasing public acceptance, economic problems resulting from the growing use of renewables and ambitious GHG reduction targets, the sector cannot resist the political pressure against it any longer. The governing parties have agreed to establish a commission called 'Growth, structural change and employment' to develop a strategy for phasing out coal-fired power plants (E3G Annual Review 2018). This Commission consists of experts and stakeholders from industry, associations, unions, the scientific community, pressure groups and politicians. Its establishment shows that the phasing-out process deserves close attention and that management policies must be implemented to ensure a soft landing for the electricity sector.

conclude that a massive early retirement of coal-fired power plants is needed, and that two to three standard 500 MW generators will need to come offline every week for fifteen years. This high rate is the result of a very large deployment of coal-fired power plants from 2004 to 2012. The early phasing out of this infrastructure will result in a significant share of stranded assets (Ansari and Holz 2020) with an impact on workers, local communities, companies and governments (van der Ploeg and Rezai 2020). The challenge is thus to manage a transition which delivers the rapid phasing out of existing fossil fuel-based infrastructure while also developing a new energy system based on low-carbon alternatives within a very short window of opportunity.

Chapter 6 similarly concludes that the transition towards a high penetration of renewable systems faces various challenges in the technical, environmental and socio-economic fields. The integration of renewables into the grid requires not only sufficient flexibility in power grids and intensive coordination with other sources of generation, but also a fundamental change in long-term planning and grid operation (see Chapter 6 for more detail on these issues).

Examples from various countries show that, compared with top-down decision-making, bottom-up policymaking involving local stakeholders could enable regions to benefit and reduce their resistance to transitions. (Kainuma et al. 2012) conclude that social dialogue is a critical condition for engaging local workers and communities in managing the transitions with the necessary support from transition assistance. They also point out that macro-level policies, training programmes, participatory processes and specific programmes to support employment creation for workers in fossil fuel-dependent industries are needed.

Examples of challenges in transitions away from using coal are given in Box 17.1.

The transition towards a high-penetration renewable system also raises concerns over the availability of rare metals for batteries like lithium and cobalt. While metal reserves are unlikely to limit the growth rate or total amount of solar and wind energy, used battery technologies and the known reserves currently being exploited are not compatible with the transition scenario due to insufficient cobalt and lithium reserves (Månberger and Stenqvist 2018). Global lithium production rose by roughly 13% from 2016 to 2017, to 43,000 Mt in 2018 (Golberg 2021). Africa has rich reserves of lithium and is expected to produce 15% of the world's supply soon (Rosenberg et al. 2019). Such reserves are found in Zimbabwe, Botswana, Mozambique, Namibia, South Africa (Steenkamp 2017) and the Democratic Republic of Congo (Roker 2018).

The demand for these resources as ingredients in rechargeable batteries is growing rapidly, with global demand for cobalt set to quadruple to over 190,000 tons by 2026. The DRC is a mineral-rich country (Smith et al. 2019a) with rich reserves of fossil fuels (coal and oil) (Buzananakova 2015). The extraction of lithium and cobalt can be environmentally and socially damaging, though its use as a principal component in most rechargeable batteries for electric vehicles and electronic smart grids affords it high sustainability value.

Chapter 10 includes a more detailed assessment of the issues with mining these rare metals, as well as the associated social problems, including exploitative working conditions and child labour, the latter a major issue that needs to be taken into consideration in transitions. Recycling batteries is also highlighted as a major supplementary policy if negative environmental side impacts are to be avoided (Rosendahl and Rubiano 2019). In the future, more attention should be paid to reducing vulnerability through subsidising R&D in rare-metals recycling, establishing systems to incentivise the collection of rare-metal waste and promoting technological progress using abundant metals as a replacement for rare metals (Rosendahl and Rubiano 2019).

17.3.2.3 Stranded Assets, Inequality and Just Transitions

As the momentum towards achieving carbon neutrality grows, the risk of certain assets becoming stranded is on the increase. International policies and the push for low-carbon technologies in the context of climate change are reducing the demand for and value of fossil fuel products. Stranded assets become devalued before the end of their economic life or can no longer be monetised due to changes in policies and regulatory frameworks, technological change, security, or environmental disruption. In short, stranded assets are 'assets that have suffered from unanticipated or premature write-down, devaluations or conversions to liabilities' (Caldecott et al. 2013).

Stranded assets are likely to 'lose economic value ahead of their anticipated useful life' (Bos and Gupta 2019). They are often described as creative when they become stranded because of innovation, competition or economic growth (Gupta et al. 2020). Divestment refers to 'the action or process of selling off subsidiary business interests or investments'. This often occurs due to changing social norms and perceptions of climate change.

Indeed, pressure is mounting on fossil fuel industries to remove their capital from heavy carbon industries. As the former Governor of the Bank of England, Mark Carney, remarked, a wholesale reassessment of prospects, especially if it were to occur suddenly, could potentially destabilise markets, sparking a pro-cyclical crystallisation of losses and a persistent tightening of financial conditions. In other words, an abrupt resolution to the tragedy of horizons itself poses a risk to financial stability (OECD 2015). The divestment narrative is also based on the view that a shift away from intensive carbon resources will be significant, as the 'less value will be destroyed, [...] the more can be re-invested in low carbon infrastructure' (OECD 2015). Social movements are critical to triggering rapid transformational change and moving away from dangerous levels of climate change (Mckibben 2012). Although divestment is hailed as a necessary action to decouple fossil fuel from growth and force carbon-intensive industries to go out of business, there is the sense that there is no shortage of investors who are willing to buy shares, so that such resources are not stranded, but simply relocated. Criticism has been levelled at the divestment movement for not having a significant impact on funding fossil fuels and not being sufficiently in tune with other wide-ranging complexities that go beyond the moral dimensions (Bergman 2018). Despite being labelled a 'moral entrepreneur', the divestment movement has the potential to disrupt

current practices in the fossil fuel industry, shape a 'disruptive innovation' and contribute to a strategy for decarbonising economies globally (Bergman 2018). Divestment is contributing to the political situation that is 'weakening the political and economic stronghold of the fossil fuel industry' (Grady-Benson and Sarathy 2016).

The risks attached to the stranding of fossil fuel assets have increased with the recent and sustained plunge in oil prices because of the global health pandemic (COVID-19) and the concomitant economic downturn, forcing demand to plummet to unprecedentedly low levels. (Oil prices have recently increased.) Many economies in transition and countries dependent on fossil fuels are going through turbulent times where asset and transition management will be critical (UNEP/SEI 2020). However, COVID-19 provides a foretaste of what a low-carbon transition could look like, especially if assets become stranded in an effort to respond to the call for action in 'building back better' and putting clean energy jobs and the just transition at the heart of the post-COVID-19 recovery (IEA 2020; United Nations General Assembly 2021). COVID-19 provides a useful proxy for issuing two alerts. First, it is a reminder of the urgency of addressing climate change, given that delaying the move away from stranded assets will further worsen climate change. Second, failure to recognise the threat from stranded assets will result in new assets becoming stranded (Rempel and Gupta 2021). Hence, the momentum towards a transformational push is resting on a new opportunity ushered in by COVID-19 to emphasise the urgency for a new departure towards rapid emissions reductions (Cronin et al. 2021).

The stranded assets narrative has focused overwhelmingly on consumption by companies: not much emphasis has been placed on the commercialisation- and investment-related aspects. In addition, other carbon-intensive activities can also run the risk of being stranded, such as cement, petrochemicals, steel and aviation (Baron and David 2015). This is why stranded assets are often referred to as having a cascading impact on several other sectors.

Transitions are broad-based and complex, involving governance structures, institutions and climate vulnerabilities, and there is a need to include historical responsibility, resource intensity and capacity differentials, thus relegating the debate across simplistic binary lines of developed versus developing countries (Carney 2016). Hence, transition processes will have to respond to several preconditions and structural inequalities related to climate finance, energy poverty, vulnerabilities and the broader macroeconomic implications associated with managing the debt burden, fiscal deficits and uneven terms of development in developing countries. In addition to structural inequalities, the COVID-19 pandemic has severely disrupted energy and food systems, and reduced the speed at which developing countries can procure new low-carbon technologies and decouple economic growth from fossil fuels (Winkler 2020). For instance, global supply-chain transition costs might be lower when compared to in-country supply chains, as became evident when COVID-19 created further disruption to renewable-energy projects (Cronin et al. 2021). Moreover, developing countries can experience difficulties in phasing out old technologies, especially if the latter has a cost disadvantage, has not benefitted from an established track record and its performance is uncertain (Bos and Gupta 2019). There

is the risk of lock-in effects related to grandfathering when emitters comply with less stringent standards.

Despite their efforts in deploying renewable energies, many developing countries are still contending with problems related to the immaturity of the current technologies and the challenges of battery storage. In short, the transition to low-carbon development must consider the challenges of renewable-energy penetration and existing energy-related vulnerabilities and inequalities. There are power asymmetries between first-comers and latecomers, especially in cases where mature technologies can be located in countries with less stringent laws and standards. Carbon leakage has implications for just transitions, as carbon-intensive industries can move their dirty industries to developing countries as a way of outsourcing the production of carbon (Bos and Gupta 2019; UNU-INRA 2020). When the challenge of climate mitigation is transferred to developing countries in the form of carbon leakage, the risks of carbon lock-in for developing countries are heightened (Bos and Gupta 2019).

Overcoming the carbon lock-in is not simply a matter of the right policies or switching to low-carbon technologies. Indeed, it would mean a radical change in the existing power relations between fossil fuel industries and their governments and social structural behaviour (Seto et al. 2016). Some actions to fix the climate change problem can themselves create injustices, thereby challenging sustainable development (Cronin et al. 2021). Not paying sufficient attention to perceptions of injustice related to the rights to development, energy and resource sovereignty can further create resistance to climate action (Cronin et al. 2021).

The shrinking carbon budget has raised questions over whether to meet our commitment to 2°C if fossil fuel resources were to be mined or left stranded, as McGlade and Ekins argue: '... [a] large portion of the reserve base and an even more significant proportion of the resource base should not be produced if the temperature rise is to remain below 2 degrees C' (McGlade and Ekins 2015). This logic means that developing countries that rely on fossil fuel extraction will need to replace their hydrocarbon revenues with other income-generating activities. Stranded assets remind most oil-producing governments that fossil fuel assets do not have a durable value and are vulnerable to politico-economic forces and fluctuations. The goal of staying within the 1.5°C temperature goal, in line with the Paris Agreement, is already part of the policy vision and planning of large fossil fuel-consuming economies. For early fossil-fuel producers, however, the reality that their resources may not yield the desired returns is often perceived as bad news, particularly in the context of the increasing depreciation of fossil fuel products.

Stranded assets raise fundamental questions related to issues of equity and just transitions:

- Who decides which resources should be stranded?
- Who shoulders the burden of the transition and losses incurred from moving away from heavy industries with associated compensation?
- How should the advantages of short-term fossil fuel exploitation be shared based on the principle of distributive justice?

The transition to a low-carbon development is wired in issues of justice and equity: how do you align carbon reductions to meet the needs of humanity? Distributive justice calls for a fairer sharing of the benefits and burdens of the transition process, while procedural justice is essentially about ensuring that the demands of vulnerable groups are not ignored in the pull to the transition. The impacts of climate change and the mitigation burdens are experienced differently by different social actors, with indigenous communities facing multiple threats and being subjected to unequal power dynamics (Sovacool 2021).

Nonetheless, the production of fossil fuels is central to many economies with numerous development implications related to rents associated with export revenues, energy security and poverty alleviation (Lazarus and van Asselt 2018). The central question is: who decides which types of carbon should be burnable or non-burnable? Hence, social equality is at the heart of the transition process, but it falls short of a response on how to chart a new road map towards carbon neutrality, especially given that fossil fuel producers and investors tend to belong to large, powerful companies and wield a great deal of influence and power, especially when their entrenched interests are at stake (Lazarus and van Asselt 2018). The question of whether developing countries should be compensated for foregoing their resources in light of their current development needs has not yielded many results and had only limited success in mobilising international finance, as demonstrated by the case of Yasuni-ITT in Ecuador (Sovacool and Scarpaci 2016). According to (Sovacool et al. 2021), affected communities and their views may be discounted and excluded from planning, which can neglect important matters such as rights, recognition and representation (Sovacool 2021).

Fossil fuel-dependent countries are doubly exposed to the vulnerability related to climate change impacts and are being targeted in the global effort to address the problem (Peszko et al. 2020). Countries that are heavily reliant on oil, coal and gas are also those most at risk from a low-carbon transition that may curtail the activities of their fossil fuel industries and render the value chains and economies associated with the exploitation of fossil fuels unviable (Peszko et al. 2020).

Developing countries in Latin America and Africa that are reliant on revenue streams from fossil fuels may not see these returns converted into much-needed infrastructure and other social and economic amenities that can reduce poverty. However, given the falling prices of renewables, developing countries do not have to face the burden of retrofitting their infrastructure to align with new low-carbon industries, since they can leapfrog technologies and shape a sustainable trajectory that is more resilient and fit for the future.

However, the transition towards a carbon-neutral world is complex and non-linear, and it will likely result in some disruptions, with manifest equality implications, given the scale of the transformation envisaged. There are parallel movements that can be observed. On the one hand, divestment initiatives are underway to move away from carbon-intensive investments. On the other hand, hydrocarbon-rich countries in some parts of the developing world are identifying new opportunities to reduce the fiscal loss associated with the loss of fossil fuel revenues. Indeed, with global investment in energy

expected to shrink by 20% in 2021, this has created fiscal challenges for countries that are heavily reliant on fossil fuel products as their main source of revenue.

Other disruptions are linked to redundant contracts and postponed or cancelled explorations, as many oil companies are diversifying their production in the wake of the pandemic and are cutting back on planned hydrocarbon investments (Denton et al. 2021). These failed concessions and disruptions have implications for the just transition, especially in developing countries without the financial ability to pull out of fossil fuels and to diversify with the same urgency as the industrialised nations (Peszko et al. 2020). For instance, in South Africa, which is seeking to divest away from coal and decarbonise its energy sector, if the transition is not properly managed, this could lead to a loss in revenue of R1.8 trillion (USD125 billion), thus compromising the government's ability to support social spending (Huxham et al. 2019). Emerging oil producers like Uganda are having to postpone the start of production. Eni and Total, two of the largest international oil and gas majors in Africa, have already signalled they are making 25% cuts to their investment in exploration and production projects in 2020, representing a EUR4 billion reduction in foreign direct investment for Total and a USD2 billion reduction for Eni (Le Bec 2020).

A poorly managed transition will reproduce inequalities, thus contradicting the very essence of a just, sustainable, inclusive transition. Revenues from oil and gas have been ploughed into social safety nets and are supporting free senior high-school education in countries such as Ghana, thus enabling the realisation of SDG 4 (quality education) (UNU-INRA 2020). The move from fossil fuels towards a low-carbon economy has economic implications for lower-income countries that are dependent on hydrocarbon resources, are endowed with significant untapped oil and gas reserves, and may not have the transitional tools to move towards low-carbon technologies or economies (Peszko et al. 2020).

The energy transition landscape is changing rapidly, and we are witnessing multiple transitions. This creates room to manage the transition in ways that will prioritise the need for workers in vulnerable sectors (land, energy) to secure their jobs and to maintain a secure and healthy lifestyle, especially as the risks multiply for those who are exposed to heavy industrial jobs and all the associated outcomes. The shift to carbon neutrality is being driven by convergent factors related to energy security and the benefits of climate mitigation, including the health impacts of air pollution and consumer demand (Svobodova et al. 2020).

Climate change is high on the global agenda, as is energy's role in decarbonising the economy, giving rise to a number of equality issues. (Oswald et al. 2020) have shown that economic inequality translates into inequality in energy consumption, as well as emissions. This is largely because people with different levels of purchasing power make use of different goods and services, which are sustained by different energy quantities and carriers (Oswald et al. 2020; Poblete-Cazenave et al. 2021).

A study by (Bai et al. 2020) shows that an increase in income inequality in China hinders the carbon abatement effect of innovations in

renewable-energy technologies, possibly even leading to an increase in carbon emissions, while a decrease in inequality of incomes is conducive to giving play to the role of this carbon abatement effect, thereby indicating that there is an important correlation between the goals of 'sustainable social development' and 'sustainable ecological development'.

India is home to one sixth of world's population but accounts for only 6.8% of global energy use and consumes only 5.25% of electricity produced globally. During the period 1990–1991 to 2014–2015, overall energy intensity in India declined from 0.007 Mtoe per billion INR of GDP to 0.004 Mtoe per billion INR of GDP, an annual average decline of 2%. The industrial sector is making the highest contribution CO₂ mitigation by reducing its energy intensity (Roy et al. 2021).

Household carbon emissions are mainly affected by incomes and other key demographic factors. Understanding the contribution of these factors can inform climate responsibilities and potential demand-side climate-mitigation strategies. A study by (Feng et al. 2021) on inequalities in household carbon the in USA shows that the per-capita carbon footprint (CF) of the highest income group (>USD200,000 yr⁻¹) with 32.3 tonnes is about 2.6 times the per-capita CF of the lowest income group (<USD15,000 yr⁻¹) with 12.3 tonnes. Most contributors of high carbon footprints across income groups in the US are heating, cooling and private transport, which reflects US settlement structures and lifestyles, heavily reliant as they are on cars and living in large houses.

Studies by (Jaccard et al. 2021) on energy in Europe shown a top-to-bottom decile ratio (90:10) of 7.2 for expenditure, 3.1 for net energy and 2.6 for carbon. Given such inequalities, these two targets can only be met through the use of carbon capture and storage (CCS), large efficiency improvements and an extremely low minimum final energy use of 28 GJ per adult equivalent. Assuming a more realistic minimum energy use of about 55 GJ per adult equivalent and no CCS deployment, the 1.5°C target can only be achieved at near full equality. The authors conclude that achieving both stated goals is an immense and widely underestimated challenge, the successful management of which requires far greater room for manoeuvre in monetary and fiscal terms than is reflected in the current European political discourse.

The 'Just Transition' concept has evolved over the years (Sweeney and Treat 2018) and is still undergoing further evolution. It emphasises the key principles of respect and dignity for vulnerable groups, the creation of decent jobs, social protection, employment rights, fairness in energy access and use, and social dialogue and democratic consultation with relevant stakeholders, whilst coping with the effects of asset-stranding or the transition to green and clean economies. The concept has come under increased scrutiny, with its protagonists emphasising the need to focus on the equality of the transition, not simply on its speed (Forsyth 2014). The emphasis on justice is also gaining in momentum, with a growing recognition that the sustainability transition is about justice in the transition and not simply about economics (Newell and Mulvaney 2013; Swilling, M. Annecke 2010; Williams and Doyon 2020). Scholars are increasingly of the view that a transition involving

low-carbon development should not replace old forms of injustice with new ones (Setyowati 2021).

The economic implications of the transition will be felt by developing countries with high degrees of dependence on hydrocarbon products as a revenue stream, as they are exposed to reduced fiscal incomes, given the low demand for oil and low oil prices, and the associated economic fallout of the pandemic. This link with stranded assets is important, but it may be overlooked, as countries whose assets are becoming stranded may not have the relevant resources, knowledge, autonomy or agency to design a fresh orientation or decide on the transition. In addition, some developing countries are dependent not only on fossil fuel revenues, but also on foreign exchange earnings from exports. This dependence comes into sharp focus when one considers that 30% of the Malaysian government's revenues are linked to petroleum products, and that Mozambique, by exploiting its newly discovered natural-gas reserves, can earn seven times the country's current GDP over a period of 25 years (Cronin et al. 2021). Thus, any attempt to accelerate the transition to low-carbon development must take into account foreign exchange, domestic revenue and employment generation, which are precisely what ensure the attractiveness of fossil fuel industries (Addison and Roe 2018).

Energy use and its deployment are sovereign matters. State responsibilities over the control and use of natural resources concern both current and future generations (Carney 2016). Climate change impacts will disable the food, water and energy systems of the most vulnerable. Therefore, the resources required to enable a just transition are predicated on good leadership and governance institutions that will support quality and justice-based transitions. Beyond energy systems, changes to land systems can benefit from sustainable land management in ways that will reduce the pressure on land for food and at the same time support carbon storage. With land coming under increased pressure, land and forest management are critical for carbon sequestration, as well as other ecosystem benefits. Extractive processes have impacts on land, and often there are few if any redistributive benefits for communities in regions where extraction takes place. In addition, extraction of strategic minerals such as cobalt, copper and lithium have been linked to violence, human rights abuses and conflict (Cronin et al. 2021).

However, in the race to achieve carbon neutrality by 2050, some of the other priorities of the transition, like climate change adaptation and its inherent vulnerabilities, might become muted, given the urgency to mitigate at all costs. Consequently, the transition imperative reduces the scope for local priority-setting and ignores the additional risks faced by countries with the least capacity to adapt. Equally, the 'just transition' is often seen through the prism of job losses and the attendant retooling and reskilling imperatives necessary to re-dynamise local businesses, especially those that may fail as a result of mine closures. It is equally important to consider current disparities in knowledge and capacity which could maintain the existing inequalities in the global regional distribution of costs and benefits. One striking example is the manufacturing of PV in India when compared to manufacturing PV in China. In China, manufacturing costs are lower than in India, as are import tariffs (Behuria 2020). Similarly, a solar industry might have greater development prospects

in one region than another given existing regional disparities in human capital, infrastructure, finance and technological development (Cronin et al. 2021).

Low-carbon transitions and equality implications will depend on local contexts, regional priorities, the points of departure of different countries in the transition and the speed at which they will want to travel. Hence, timing and scope are important elements that are associated more with a quality transition than a race to the bottom. To date, the debate has had some obvious blind spots, not least considerations of power, politics and political economy (Denton et al. 2021). Certainly, the transition will create winners and losers, as well as stakeholders that can frame their economic interests so as to determine the orientation, pace, timing and scope of the transition.

The determination of a just transition is complex and not simply dependent on the allocation of perceived risks or solutions, but rather on how risks and solutions are defined (Forsyth 2014). Acting urgently to achieve environmental solutions or meet transition imperatives has certain risks given the need to go beyond commonplace definitions of the just transition by emphasising the distributive or procedural aspects. The framing of policies to align with fast and low-cost mitigation without paying sufficient attention to social and economic resilience creates its own potential risks and can enhance social vulnerability rather than address it. The need to distribute climate change solutions must not delegitimise appropriate economic growth strategies, nor indeed create the additional risks of policy imposition. Perceptions of justice with regard to environmental problems and solutions matter equally. Hence, the types of transition pathway that are chosen may have equality implications. Mitigation at all costs, if done 'cheaply and crudely', can create additional problems for social justice and inclusive development (Forsyth 2014).

The assumption that the benefits of mitigation are enough to offset trade-offs with other policy objectives can be questioned. If one accepts the argument that not all adaptation addresses vulnerability concerns (Kjellén 2006), and that some adaptation strategies can heighten vulnerabilities if there are flaws in their design and implementation, then the same logic applies, namely that not all mitigation is necessarily beneficial. Hence the emphasis on the transition resulting from mitigation should be placed not only on speed or cost-effectiveness, but also on the legitimacy of the actions, and whether the transition is well designed or not. In short, justice is not always a shorthand for acting ethically, but rather a point of reasoning on what is considered legitimate. Planning for the transition often discounts human rights and social inclusivity that can occur as the result of a rapid transition. The emphasis should be placed on the management of the transition rather than the speed – for instance, if in the rush to build new hydropower energy sources implies that populations are displaced, then this constitutes a human rights violation (Castro et al. 2016; Piggot et al. 2019).

Ambitious climate goals can increase the urgency of mitigation and accelerate the speed at which carbon neutrality is achieved. However, if the transition is done with speed, then this will leave diversification efforts stymied, particularly in developing countries that are highly dependent on fossil fuel revenue streams (UNEP/SEI

2020). Transition decisions and policies may also have far-reaching gendered implications, as the closure of mines is often linked to several ancillary business impacts where men are laid off and women may have to take on multiple jobs to compensate for the reduction in the household's income (Piggot et al. 2019; UNU-INRA 2020).

A just transition holds out the prospects for alternative high-quality jobs, public-health improvements and an opportunity to focus on well-being and prosperity, with spillover benefits to urban areas and economic systems. Nonetheless, countries that transition from fossil fuels experience different challenges, different levels of dependence and have different capacities to transition. There will be countries with lower capacity and higher dependence, and vice versa (UNEP/SEI 2020).

Deciding on matters of justice is essential to the transition, and there are several inherent questions to consider when thinking through the allocation of costs and benefits, as is the case with distributive justice. How matters are defined and who defines matters such as the timing of phasing out, prioritising which energy sources need to be phased out and who might be affected are all political economy questions (Piggot et al. 2019).

Similarly, when considering issues of procedural justice, there are matters related to interests, participation and power dynamics that are essential to the process, but that might also subvert the process, depending on whose rights, whose participation and whose power are being put in jeopardy (Forsyth 2014; Piggot et al. 2019). Hence, both distribution and procedure matter, as do inter-generational and intra-generational equity in planning transitions. Six critical variables can shape or inhibit the transition process. These are dependence, timing, capacity, agency, scope and inclusion (Denton et al. 2021).

Dependence, or the extent to which a country may depend on revenue streams from fossil fuels, will determine its ability to manage the transition from fossil fuels. Countries who rely on the proceeds from hydrocarbon resources as economic rents to support fiscal income and spending on public service-related needs such as education, health and infrastructure, export earnings and foreign exchange reserves will have greater difficulties in foregoing their fossil fuel resources.

Timing: the transition pathway has to be aligned with a timetable which is anchored in national development priorities. For example, South Africa's Integrated Resource Planning indicates that the transition away from coal, if not aligned with national development priorities, will reproduce new forms of inequality. In addition, if the transition is imposed and its timing is not organic, then this might also produce social inequalities.

Capacity: transitions need to reflect spaces and planning. If knowledge about the transition pathway is not adequately mastered or in place, this can disable the process or steer it in the wrong direction. Capacity also relates to several attributes, including technical, governance, institutional, technologies, and economic resources to manage the transition. Poorer countries will have

difficulties in managing all these resources, as well as absorbing the costs associated with the transition (UNEP/SEI 2020).

Agency: transitions are inherently about the sovereign right to determine one's orientation towards low-carbon development. However, given the urgency to stick to the Paris Agreement and the new conditionalities related to post-COVID stimulus packages, the absence of agency to deal with the transition might jeopardise its flow, orientation and pace (Newell and Mulvaney 2013).

Scope: the extent to which the transition is rolled out and its potential impacts. If transition policies are ambitious in making commensurate diversification investments, this may enable job creation, but it may also affect employees who are insufficiently prepared to undertake new jobs and skills.

Inclusion: who is considered in the transition process and how their interests and risks are assessed are important aspects of transition pathways. Stakeholders with strong vested interests may resist the transition, especially as it moves towards diversification activities and policies.

17.3.3 Cross-sectoral Transitions

Transitions will involve multiple sectoral- and cross-sectoral policies. Section 17.3.3 presents a range of studies and conclusions on the relationship between climate change mitigation goals and meeting the SDGs in order to identify major synergies and trade-offs. The interactions are manifold and complex (Nilsson et al. 2016; Pradhan et al. 2017) (Section 4.3.1.2). Here we draw on conclusions from sectoral chapters and add additional studies as a basis for drawing more general conclusions about agriculture, food and land use, the water-energy-food nexus, industry, cities, infrastructure and transportation, cross-sectoral digitalisation, and mitigation and adaptation relations.

17.3.3.1 Agriculture, Forestry and Other Land Uses (AFOLU)

Sustainable development and mitigation policies are closely linked in the agriculture, food and land-use sectors. We assess synergies and trade-offs between meeting the SDGs and reducing GHG emissions within the sectors based on modelling studies and case studies illustrating how trade-offs between SDG 2 (zero hunger, biomass for energy) and SDG 15 (life on land) can be addressed by cross-sectoral mitigation options.

Chapter 7 emphasises the high expectations on land to deliver mitigation, yet the pressures on land have grown with population, dietary changes, the impacts of climate change and the conversion of uncultivated land to agriculture and other land uses. Agriculture, forestry and other land uses (AFOLU) are expected to play a vital role in the portfolio of mitigation options across all sectors. The AFOLU sector is also the only one in which it is currently feasible to achieve carbon dioxide removal (CDR) from the atmosphere, including afforestation/reforestation (A/R), improved forest management and soil carbon sequestration (SCR) (Chapters 7 and 12). The AFOLU sector

has a significant mitigation potential, with many scenarios showing a shift to net-negative CO₂ emissions during the 21st century. Total cumulative AFOLU CO₂ sequestration varies widely across scenarios, with as much as 415 GtCO₂ being sequestered between 2010 and 2100 in the most stringent mitigation scenarios. The largest share of net-GHG emissions reductions from AFOLU in both the 1.5°C and 2°C scenarios is from forestry-related measures, such as afforestation, reforestation and reduced deforestation. Afforestation, reforestation and forest management result in substantial CDR in many scenarios. CO₂ and CH₄ show larger and more rapid declines than N₂O, an indication of the difficulties of reducing N₂O emissions in agriculture (Chapter 3).

The Global Assessment on Biodiversity and Ecosystem Services Report (IPBES 2019, Chapter 5) assessed the relationship between meeting the goals of the Paris Agreement and SDGs 2 (zero hunger), 7 (affordable and clean energy) and 15 (life on land). It concluded that a large expansion of the amount of land used for bioenergy production would not be compatible with these SDGs. However, combining bioenergy options with other mitigation options, like more efficient land management and the restoration of nature, could contribute to welfare improvements and to accessing food and water. Demand-side climate-mitigation measures, like energy-efficiency improvements, reduced meat consumption and reduced food waste, were considered to be the most economically attractive and efficient options in order to support low GHG emissions, food security and biodiversity objectives. Implementing such options, however, can involve challenges in terms of lifestyle changes (IPBES 2019).

The potential joint contribution of food and land-use systems to sustainable development and climate change has also been addressed in policy programmes by the UN, local governments and the private sector. These programmes address options for pursuing sustainable development and climate change jointly, such as agroforestry, agricultural intensification, better agriculture practices and avoided deforestation. (Griggs and Stafford-Smith 2013) assess production- and consumption-based methods of achieving joint sustainability and climate-change mitigation in food systems, concluding that efficiency improvements in agricultural production systems can provide large benefits. Given the expectations of high levels of population growth and the strong increase in the demand for meat and dairy products, there is also a need for the careful management of dietary changes, as well for those areas which could be used most effectively for livestock and plant production.

Loss of biodiversity has been highlighted in several studies as a major trade-off of the low stabilisation scenarios (Prudhomme et al. 2020). A wide range of mitigation and adaptation responses – for example, preserving natural ecosystems such as peatland, coastal lands and forests, reducing the competition for land, fire management, soil management and most risk-management options – have the potential to make positive contributions to sustainable development, ecosystems services and other social goals (McElwee et al. 2020). (Smith et al. 2019a) also stressed that agricultural practices (e.g., improving yields, agroforestry), forest conservation (e.g., afforestation, reforestation), soil carbon sequestration (e.g., biochar addition to soils) and the removal of

carbon dioxide (e.g., BECCS) could contribute to climate change mitigation (Smith et al. 2019a). However, there are also options that could improve biodiversity if they were implemented jointly with climate change mitigation in AFOLU. In their study, (Leclère et al. 2020) show that increasing conservation management, restoring degraded land and generalised landscape-level conservation planning could be positive for biodiversity. In general, the ambitious conservation efforts and transformations of food systems are central to an effective post-2020 biodiversity strategy.

The IPCC Special Report on Climate Change and Land (IPCC 2019) emphasises the need for governance in order to avoid conflict between sustainable development and land-use management. It states: 'Measuring progress towards goals is important in decision-making and adaptive governance to create common understanding and advance policy effectiveness'. The report concludes that measurable indicators are very useful in linking land-use policies, the NDCs and the SDGs.

One example of an area where special governance efforts have been called for is the protection of forestry, ecosystem services and local livelihoods in a context of the large-scale deployment of high-value crops like palm oil, short-term, high income-generating activities and sustainable development. Serious challenges are already being seen within these areas according to (IPBES 2019).

Palm oil is one example of a product with potentially major trade-offs between meeting the SDGs and climate change mitigation in the agriculture, forest and other land uses (AFOLU) sector. Currently the area under oil palms is showing a tremendous increase, mostly in forest conversions to oil-palm plantations (Austin et al. 2019; Gaveau et al. 2016; Schoneveld et al. 2019). The conversion of peat swamp forest and mineral forest to oil palms will yield different amounts of CO₂. A study by (Novita et al. 2020) shows that the carbon stock of primary peat-swamp forest was 1770 MgC ha⁻¹ compared to a carbon stock of oil palm of 759 MgC ha⁻¹. The study conducted by Guillaume et al. shows that the carbon stock in mineral soils was 284 MgC ha⁻¹ compared to that in rainforest, which was 110.76 MgC ha⁻¹ (Guillaume et al. 2018).

Restoring peatlands is one of the most promising strategies for achieving nature-based CDR (Girardin et al. 2021; Seddon et al. 2021). A study by (Novita et al. 2021) shows that significantly different CO₂ emissions for different land-use categories are influenced more by the water-table depth and latitude position for those locations relative to other observed parameters, such as bulk density, air temperature and rainfall.

Given that the frequent peatland fires in Indonesia were caused by land clearances in the replanting season, multi-stakeholder collaboration between oil-palm plantations, local communities and local governments over practices such as zero burning when clearing land might be one of the most effective ways to reduce the deforestation impact of oil palm (Jupesta et al. 2020). Behavioural changes as a mitigation option have been suggested as a major factor in aligning sustainable development, climate change and land management. In the absence of the policy intervention, the expansion

of oil-palm plantations has provided limited benefits to indigenous and Afro-descended communities. Even when oil-palm expansion improves rural livelihoods, the benefits are unevenly distributed across the rural population (Andrianto et al. 2019; Castellanos-Navarrete et al. 2021). In any case, while oil-palm production can improve smallholders' livelihoods in certain circumstances, this sector offers limited opportunities for agricultural labourers, especially women (Castellanos-Navarrete et al. 2019).

Economy-wide mitigation costs can be effectively limited by lifestyle, technology and policy choices, as well as benefitting from synergies with the SDGs. Synergies come from the consumption side by managing demand. For example, reducing food waste leads to resources being saved because water, land use, energy consumption and greenhouse gas emissions are all reduced (Chapter 3).

Chapter 12 emphasised that diets high in plant protein and low in meat, in particular red meat, are associated with lower GHG emissions. Emerging food-chain technologies such as microbial, plant, or insect-based protein promise substantial reductions in direct GHG emissions from food production. The full mitigation potential of such technologies can only be realised in low-GHG energy systems.

(Springmann et al. 2018) conclude that reductions in food waste could be a very important option for reducing agricultural GHG emissions, the demand for agricultural land and water, and nitrogen and phosphorous applications. In addition to the possibility to reduce food waste, their study analysed several other options for reducing the environmental effects of the food system, including dietary changes in the direction of healthier, more plant-based diets and improvements in technologies and management. It was concluded that, relative to a baseline scenario for 2050, dietary changes in the direction of healthier diets could reduce GHG emissions by 29% and 5–9% respectively in a dietary-guideline scenario, and by 56% and 6–22% respectively in a more plant-based diet scenario. Demand-side, service-oriented solutions vary between and within countries and regions, according to living conditions and context. Avoiding food waste reduces GHG emissions substantially. Dietary shifts to plant-based nutrition lead to healthier lives and reduce GHG emissions (Section 5.3).

A similar study also found a positive impact from zero food waste. The 'no food waste' scenario could decrease global average food calorie availability by 120 kcal person⁻¹ d⁻¹ and protein availability by 4.6 g protein person⁻¹ d⁻¹ relative to their baseline levels, thus reducing required crop and livestock production by 490 and 190 Mt respectively. This lower level of production reduces agricultural land use by 57 Mha and thus mitigates the associated side effects on the environment. The lower levels of production also reduce the requirements for fertilisers and water by 10 Mt and 110 km³ respectively, and GHG emissions are reduced by 410 MtCO₂-eq yr⁻¹ relative to the 2030 baseline. Reducing food waste can contribute to lessening the demand for food, feed and other resources such as water and nitrogen, reducing the pressure on land and the environment while ending hunger (Hasegawa et al. 2019).

In 2007, Britain launched a nationwide initiative to reduce household food waste, which achieved a 21% reduction within five years

(FAO 2019). The basis of this initiative was the 'Love Food, Hate Waste' radio, TV, print and online media campaign run by a non-profit organisation, the Waste and Resources Action Programme (WRAP). The campaign raised awareness among consumers about how much food they waste, how it affects their household budgets and what they can do about it. This initiative collaborated with food manufacturers and retailers to stimulate innovation, such as resealable packaging, shared meal-planning and food-storage tips. The total implementation costs during the five-year period were estimated at GBP26 million, from which it was households that derived the most benefit, estimated to be worth GBP6.5 billion. Local authorities also realised a substantial GBP86 million worth of savings in food-waste disposal costs. As for the private sector, the benefits took the form of increased product shelf lives and reduced product loss. While households started to consume more efficiently and companies may have experienced a decline in food sales, the latter also stated that the non-financial benefits, such as strengthened consumer relationships, had offset the costs.

The Asia Pacific Economic Cooperation (APEC) group of countries has also created several types of public-private partnership to tackle food waste and reduce losses. Most of these partnerships are focused on food-waste recycling in both developed and developing countries (Rogelj et al. 2018). APEC members stated that knowledge-sharing and improved policy and project management were the most important advantages of public-private partnerships.

The inextricably intertwined factors in decision-making are influenced by the characteristics of the person, in interaction with the characteristics of more sustainable practices and products, which interact with a particular context that includes the immediate environment (e.g., household, farm), the indirect environment (e.g., community) and macro-environmental factors (e.g., the political, financial and economic contexts) (Hoek et al. 2021). Hence, to influence people to make decisions in favour of sustainable food production or consumption, a wider perspective is needed on decision-making processes and behavioural change, in which individuals are not targeted in isolation, but in interaction with this wider systemic environment.

In conclusion, the AFOLU sector offers many low-cost mitigation options, which, however, can also create trade-offs between land use for food, energy, forest and biodiversity. Some options can help to mitigate such trade-offs, like agricultural practices (e.g., improved yields, agroforestry), forest conservation (e.g., afforestation, reforestation), soil carbon sequestration (e.g., biochar addition to soils) and the removal of carbon dioxide (e.g., BECCS), which could contribute to climate change mitigation. Lifestyle changes, including dietary changes and reduced food waste, are tightly embedded in modes of behaviour that are influenced by the immediate environment (e.g., household, farm), the indirect environment (e.g., community) and macro-environmental factors (e.g., political, financial and economic contexts). Achieving zero food waste could reduce the demands for land (SDG 15), water use (SDG 6) and chemical fertilisers (SDG 9), leading to GHG emissions reductions (SDG 13) by encouraging sustainable consumption and production practices (SDG 12).

17.3.3.2 Water-Energy-Food Nexus

This section addresses the links between water, energy and food in the context of sustainable development and the associated synergies and trade-offs, with links to related chapters. The focus outline includes scoping and the relationship with the SDGs, general climate change impacts on global water resources, energy-system impacts and the relationship to renewables, enabling strategies, trade-offs and cross-sectoral implications (see also Chapter 12), nexus-management tools and strategies, and a box with examples from India and South Africa.

The continually increasing pressures on natural resources, such as land and water, due to the rising demands from increases in population and living standards, which also require more energy, emphasises the need to integrate sustainable planning and exploitation (Bleischwitz et al. 2018).

The water-energy-food nexus (WEFN) is at the epicentre of these challenges, which are of global relevance and are the focus of policies and planning at all levels and sectors of global society. The nexus between water, energy and food (Zhang et al. 2018) is tight and complex, and needs careful attention and deciphering across spatio-temporal scales, sectors and interests to balance proper management and trade-offs and to pursue sustainable development (Biggs et al. 2015; Dai et al. 2018; Hamiche et al. 2016). The WEFN touches upon the majority of the UN's SDGs, such as SDG 2, SDG 6, SDG 7 and SDGs 11–15 (Bleischwitz et al. 2018), and deals with basic commodities, thus guaranteeing the basic livelihoods of the global population.

The task of gaining an improved understanding of WEFN processes across disciplines such as the natural sciences, economics, the social sciences and politics has been further exacerbated by climate change, population growth and resource depletion. In light of the system of interlinkages involved, the WEFN concept essentially also covers land (Ringler et al. 2013) and climate (Brouwer et al. 2018; Sušnik et al. 2018), and can be further assessed in light of the relevant economic, ecological, social and SDG aspects (Fan et al. 2019a). The nexus approach was introduced in the early 2010s, when it was argued that advantages could be gained by adopting a nexus approach with regard to cross-sectoral and human–nature dependencies and by taking externalities into account (Hoffmann 2011). Hence, within the nexus, obvious trade-offs exist with competing interests, such as water availability versus food production.

Climate change is projected to impact on the distribution, magnitude and variability of global water resources. A yearly increase in precipitation of 7% globally is expected by 2100 in a high-emissions scenario (RCP8.5), although with significant inter-model, inter-regional and inter-temporal differences (Giorgi et al. 2019). Similarly, extreme events related to the water balance, such as droughts and extreme precipitation, are projected to shift in the future (RCP4.5) towards 2100: for example, the number of consecutive dry days is projected to increase in the Mediterranean region, southern Africa, Australia and the Amazon (Chen et al. 2014). In impact terms, an increase of 20–30% in global water use is expected by 2050 due to the industrial and domestic demand for water. Already 4 billion people

experience severe water scarcity for at least one month per year (WWAP-UNESCO 2019).

Globally, climate change has been shown to cause increases of 4%, 8% and 10% in the share of population being exposed to water scarcities under the 1.5°C, 2°C and 3°C scenarios for global warming respectively (RCP8.5) (Koutroulis et al. 2019). At the same time, climate change is projected to cause a general increase in extreme events and climate variability, placing a substantial burden on society and the economy (Hall et al. 2014). Other than the human influence on the global hydro-climate, human activities have been shown to surpass even the impact of climate change in low to moderate emission scenarios of the water balance (Haddeland et al. 2014). Similar conclusions have been found by (Destouni et al. 2013; Koutroulis et al. 2019).

An obvious consequence of the impact of climate change on future hydro-climatic patterns is the fact that the energy system is projected to experience vast impacts through climate change (Fricko et al. 2016; Van Vliet et al. 2016a; van Vliet et al. 2016b) (Chapter 6). In the short run, where fossil fuel sources make up a significant share of the global energy grid, climate impacts related to water availability and water temperatures will affect thermoelectric power generation, which relies mainly on water cooling (Larsen and Drews 2019; Pan et al. 2018); water is also used for pollution and dust control, cleaning, and so on (Larsen et al. 2019). Currently, 98% of electricity generation relies on thermoelectric power (81%) and hydropower (17%) (van Vliet et al. 2016a).

Of these thermoelectric sources, the vast majority employ substantial amounts of water for cooling purposes, although there is a trend currently towards implementing more hybrid or drier forms of cooling (Larsen et al. 2019).

The renewable-energy conversion technologies that are currently dominant globally and are projected to remain so are less vulnerable to water deficiencies than fossil-based technologies, since no cooling is used. These renewable-energy conversion sources include, for example, wind, solar PV and wave energy. The implementation of such sources will, in the longer run, have the potential to reduce water usage by the energy sector substantially (Lohrmann et al. 2019). Also, an increasing share of renewables within desalination, as well as improved irrigation efficiencies, have been shown to potentially improve the inter-sectorial WEFN water balance (Lohrmann et al. 2019; Caldera and Breyer 2020). Some less dominant renewable-energy technologies do use water for cooling, such as geothermal energy and concentrating solar power (CSP), if wet cooling is employed. Despite the general detachment from water resources, wind and solar PV, for example, are highly dependent on climate change patterns, including variability depending on future energy-storage capacities and on/off-grid solutions (Schlott et al. 2018). Furthermore, regardless of whether or not they are based on renewables, climate change will affect energy usage across sectors, such as heating and cooling in the building stock. The energy systems in question need to be able to handle variations and extremes in demand (Larsen et al. 2020).

For the 2080s compared to 1971–2000, an increase of 2.4% to 6.3% in the global gross hydropower potential, from the hydrological side

alone, is seen across all scenarios (van Vliet et al. 2016a) (Chapter 6). Alongside the global increase in hydropower potential, the global mean water-discharge cooling capacity, which also relates to water temperatures, experiences a decrease of 4.5% to 15% across the scenarios. In very general and global terms, when combined, these changes support the shift towards sources of renewable energy, including hydropower, in the energy mix. When it comes to ensuring stability in the management of the electricity grid, hydro-climatological extremes have the potential to pose vast difficulties in certain regions and/or seasons depending on the nature of the energy mix (Van Vliet et al. 2016c). Van Vliet et al. (2016b) showed significant reductions in both thermoelectric and hydropower electricity capacities, exemplified by the 2003 European drought, which resulted in reductions of 4.7% and 6.6%, respectively.

The energy sector is vulnerable to production losses caused mainly by heatwaves and droughts, whereas coastal and fluvial floods are also responsible for a large relative share of the energy sector's vulnerability, as assessed by (Forzieri et al. 2018) for Europe in 2100. In total, heatwaves and droughts will be responsible for 94% of the damage costs to the European energy system compared to 40% today. Similarly, (Craig et al. 2018) show that, despite potentially minor spatio-temporally aggregated differences for various energy-system components, such as demand, thermoelectric power, wind, and so on, the aggregated impact of climate change across these components will cause a significant impact on the energy system, as currently exemplified by the USA. In terms of investments and management, it is important to unravel these cross-component relations in light of the projected nature of the future climate.

In the ongoing transition towards renewable sources of energy (see also Chapters 3, 4 and 6), the impact of the hydro-climate on energy production continues to be highly relevant (Jones and Warner 2016). As the shares of thermoelectric energy production in the energy grid go down along with the introduction of thermoelectric cooling technologies using smaller amounts of water, new energy sources and technologies are being introduced, and existing sources scaled up. Of these, hydropower, wind and solar energy are the key energy sources currently and will be in the near future, making up 2.5% and 1.8% of the total global primary energy supply in 2017 respectively (IEA 2019). Wind and solar energy are directly independent of water in themselves, but are dependent on atmospheric conditions related to processes that also drive the water balance and circulation. Hydropower, on the other hand, is directly influenced by and dependent on the supply of water, while at the same time being an essential counter-component to seasonality and climatological variation, as well as to current and future demand curves and diurnal variations, as against wind and solar energy (De Barbosa et al. 2017).

Furthermore, policy instruments in power-system management, here exemplified by hydropower in a climate-change scenario, have been shown to enhance energy production during droughts (Gjorgiev and Sansavini 2018). The significant influence of variation in the planning of renewable energy for the 21st century has also been highlighted by (Bloomfield et al. 2016). At the same time, the integration of renewables must account for lower thermoelectric efficiencies and capacities due to increases in temperature

(van Vliet et al. 2016a), power-plant closures during extreme weather events due to a lack of cooling capacity (Forzieri et al. 2018), and further efficiency reductions and penalties following the implementation of CCS technologies in the effort to reach the GHG mitigation targets (Byers et al. 2015). However, more recent studies find more promising amounts of water being used for energy conversion (IEAGHG 2020; Magneschi et al. 2017).

The extraction, distribution and wastewater processes of anthropogenic water-management systems similarly use vast amounts of energy, making the proper management of water essential to reduce energy usage and GHG emissions (Nair et al. 2014) Chapter 11). One study reports that the water sector accounts for 5% of total US GHG emissions (Rothausen and Conway 2011). Within the WEFN, there is an obvious trade-off between water availability and food production, competing demands that pose a risk to the supply of the basic commodities of food, energy and water in line with the SDGs (Bleischwitz et al. 2018; Gao et al. 2019), all of which have the potential for inter-sectorial or inter-regional conflicts (Froese and Schilling 2019). Currently, 24% of the global population live in regions with constant water-scarce food production, and 19% experience occasional water scarcities (Kummu et al. 2014). To counterbalance the demand for food and comestibles in regions that experience constant or intermittent supplies, transportation is needed, which in itself requires suitable infrastructure, energy supplies, a well-functioning trading environment and support policies. Of the 2.6 billion people who experience constant or occasional water scarcities in food production, 55% rely on international trade, 21% on domestic trade and the remainder on water stocks (Kummu et al. 2014).

The relations between the influence of hydro-climatic variability, socio-economic conditions and patterns of water scarcity have been addressed by (Veldkamp et al. 2015). A key finding of this study was the ability of the hydro-climate and the socio-economy to interact, enforcing or attenuating each other, though with the former acting as the key immediate driver, and the influence of the latter emerging after six to ten years.

The trade-offs between competing demands have been investigated on a continental scale in the US Great Plains, highlighting the influence of irrigation in mitigating reductions in crop yields (Zhang et al. 2018). Despite crop-yield reductions of 50% in dry years compared to wet years, a key conclusion was that the irrigation should be counterbalanced against general water and energy savings within the context of trade-offs. In East Asia, the WEFN has been quantified, highlighting obvious trade-offs between economic growth, environmental issues and food security (White et al. 2018). This same study also highlights the concept of a virtual WEFN that includes water embodied within products that are traded and shipped. (Liu et al. 2019) find an urgent need for proper assessment methods, including of trade within the WEFN, due to the significant resource allocations.

Within the WEFN, the implementation of policies to achieve low stabilisation targets is strongly linked to sustainable development within the water sector with regard to water management and

water conservation, indicating that additional coherence in policies affecting the water, energy and food sectors (among others) will be critical in achieving the SDGs (Chapter 7). Subsidised fertilisers, energy and crops can drive unsustainable levels of water usage and pollution in agriculture. More than half the world's population, roughly 4.3 billion people in 2016, live in areas where the demand for water resources outstrips sustainable supplies for at least part of the year. Irrigated agriculture is already using around 70% of the available freshwater, and the large seasonal variations in water supply and the needs of different crops can create conflicts between water needs across sectors at different time scales (Wada et al. 2016). However, as there is little potential for increasing irrigation or expanding cropland (Steffen et al. 2015), gaps in food production gaps must be closed by increasing productivity and cropping densities on currently harvested land by increasing either rain-fed yields or water-use efficiency (Alexandratos and Bruinsma 2012).

It has been argued that applying an integrated approach to water-energy-climate-food resource management and policymaking is highly beneficial in properly addressing the co-benefits and trade-offs (Brouwer et al. 2018; Howells et al. 2013), accommodating the SDGs (Rasul 2016) and, in general, assessing enabling strategies to improve resource efficiency (Dai et al. 2018). For an integrated approach to analysing the WEFN, a number of modelling approaches, tools and frameworks have been proposed (Brouwer et al. 2018; de Strasser et al. 2016; Gao et al. 2019; Larsen et al. 2019; Smajgl et al. 2016), often involving multi-objective calibration. Such tools enable decision-makers to evaluate the optimal water-allocation and energy-saving solutions for the specific geography in question. As an example, (Scott 2011) found the higher transportability of electricity, compared to water, pivotal in water-energy adaptation solutions in the USA, while arguing for the additional coordination of water and energy policies as a key instrument in balancing the trade-offs.

Common to all these integrated efforts is the challenge involved in making comparisons across studies due to the combined complexities of assumptions, model codes, regions, variables, forcings, and so on. To accommodate these challenges, (Larsen et al. 2019) suggest employing shared criteria and forcing data to enable cross-model comparisons and uncertainty estimates, as also highlighted by (Brouwer et al. 2018). Other limitations in current WEFN research are partial system descriptions, the failure to address uncertainties, system boundaries, and evaluation methods and metrics (Zhang et al. 2018). The lack of proper access to WEFN data and data quality has been highlighted by (D'Odorico et al. 2018; Larsen et al. 2019). Furthermore, gaps have been identified between theory and end-user applications in the lack of any focus on food nutritional values as opposed to calories alone, in the understanding of water availability in relation to management practices, in integrating new energy technologies and in the resulting environmental issues (D'Odorico et al. 2018).

Therefore, looking ahead, future fields of WEFN research should provide greater insights into all these aspects. Holistic frameworks have been put forward to facilitate methods of WEFN management by focusing on, for example, the geographical complexities with regard to transboundary challenges within hydrological catchments

(de Strasser et al. 2016), aligning policy incentives (Rasul 2016) and making synergies and trade-offs in relation to WEFN SDG targets (Fader et al. 2018), and so on. The roles of all levels of government in optimal WEFN management are also highlighted in (Kurian 2017), especially with regard to shaping the behaviour of individuals. Furthermore, (Kurian 2017) highlights the challenges involved in science and policy communicating with one another and in the provision of optimal instruments and guidelines. Engaging non-experts and end-users in scientific processes is seen as essential to capturing previous failures and successes, and to ensure that understanding the challenges is updated to help shape the research questions.

Coordination of water use across different sectors and deltas is an important factor in sustainable water management. Examples of instruments and policies that support this from India and Sub-Saharan Africa in relation to the groundwater crisis are given below. India is the world's largest user of groundwater for irrigation, which covers more than half of the country's total irrigated agricultural area, is responsible for 70% of food production and supports more than 50% of the population (700 million people) (Chapter 7). However, excessive extraction of groundwater is depleting aquifers across the country, and falls in the water table have become pervasive. Improved water-use efficiency in irrigated agriculture is being considered, both globally and in India, as a way of meeting future food requirements with increasingly scarce water resources (Fishman et al. 2015).

The entirety of Sub-Saharan Africa has an undeveloped potential for groundwater exploitation, despite the general perception of a global groundwater crisis, this being due to the absence of services to support groundwater development (Cobbing 2020). It is estimated that most Sub-Saharan countries in Africa utilise less than 5% of their national sustainable yields (Cobbing and Hiller 2019). The initial tool for driving sustainable groundwater exploitation is a change in the narrative of a lack of resources in order to stimulate increased agricultural production and increased fulfilment of the SDGs (Cobbing 2020). Quantitative measures of actual groundwater vulnerability based on multiple indicators have been calculated by, for example, (van Rooyen et al. 2020), showing that 20.4% of South Africa's current water resources are highly vulnerable and are projected to worsen fifty years into the future.

Despite the positive perspectives regarding Sub-Saharan groundwater resources, the 2015–2017 water crisis in South Africa, including in Cape Town, clearly predicts vulnerability to climate variability (Carvalho Resende et al. 2019), which is predicted to increase. Serving as inspiration for the future mitigation of water depletion, (Olivier and Xu 2019) suggest certain governance tools to improve the diversification of water sources and the management of existing supplies.

17.3.3.3 Industry

Industrial transformation is a core component in achieving sustainable development. Across all industrial sectors, the development and deployment of innovative technologies, business models and policy approaches at scale will be essential in accelerating progress both with meeting the economic and social development goals and with achieving low emissions. In this section, we assess the synergies and

trade-offs between mitigation options and the SDGs, with a specific focus on asking whether economic growth and employment creation can work jointly with climate actions and other SDGs in least developed and developing countries. Examples of synergies and trade-offs are provided based on the conclusions of Chapter 9 on the building sector and Chapter 11 on industry. The potential for greening industry is discussed in relation to eco-industrial parks, with examples from Ethiopia, China, South Africa and Ghana.

Chapter 11 concludes that achieving net zero emissions from the industrial sector are possible. This will require the provision of electricity free from greenhouse gas (GHG) emissions, including from other energy carriers, increased electrification, low-carbon feedstocks, and a combination of energy efficiency, reduced demand for materials, a more circular economy, electrification and carbon capture, use and storage (CCUS).

The potential co-benefits of mitigation options in industry has been mapped out in Chapter 11 in relation to five categories of mitigation options: material efficiency and reductions in the demand for materials, the circular economy and industrial waste, carbon capture and storage, energy efficiency, and electrification and fuel switching (Figure 11.15). In particular, the first two categories of options are assessed as having several co-benefits for the SDGs, including SDGs 3, 5, 7, 8, 9, 11, 12, and 15. Some studies also point out the potential trade-offs in respect of employment and the costs of cleaner production. The other options primarily impact on climate actions, decent work and employment, and industry as such.

(Okereke et al. 2019) offer important generic conclusions on green industrialisation and the transition based on a study of socio-technical transition in Ethiopia. The importance of drivers for changes in terms of clear policy goals and government support for green growth and climate policies, as well as support from a strong culture of innovation, is emphasised. The study also identifies key barriers in relation to stakeholder interactions, the availability of resources and the ongoing tensions between ambitions for high economic growth and climate change. Green innovation in industry critically depends on regulations. (Gramkow and Anger-Kraavi 2018) have assessed the role of fiscal policies in greening Brazilian industry based on an econometric analysis of 24 manufacturing sectors. They conclude that instruments like low-cost finance for innovation and support to sustainable practices effectively promote green innovation.

(Luken 2019) have assessed the drivers, barriers and enablers for green industry in Sub-Saharan Africa, concluding that major barriers exist related to material and input costs, as well as product requirements in foreign markets, and that as a result there are trade-offs between economic and environmental performance. Studies of ten countries are reviewed, and although they suffer from limited information, they conclude similarly that further progress is being hindered by poor access to finance and weak government regulation. (Greenberg and Rogerson 2014). They similarly conclude that the greening of industry in South Africa is lagging behind due to economic barriers and weak governance, despite its high priority in government planning and among international partners.

Ghana has launched a 'One District One Factory' (1D1F) initiative, aimed at establishing at least one factory or enterprise in each of Ghana's 216 districts as a means of creating economic growth poles to accelerate the development of these areas and create jobs for the country's increasingly youthful population. The policy aims to transform the structure of the economy from one dependent on the production and export of raw materials to a value-added industrialised economy driven primarily by the private sector (Yaw 2018). As has been pointed out by (Mensah et al. 2021), in its initial design the programme did not take environmental quality into consideration. Although it was successful in creating economic growth, exports and employment, the environmental impacts have been negative. It has therefore been recommended that environmental regulations be imposed on foreign investments. Similar conclusions have been drawn by (Solarin et al. 2017).

Chapter 11 concludes that eco-industrial parks, in which businesses cooperate with each other in order to avoid environmental pressure and support sustainable development, have delivered several benefits in relation to overall reductions in both virgin materials and final wastes, implying significant reductions in industrial GHG emissions. Due to these advantages, eco-industrial parks have been actively promoted, especially in East Asian countries such as China, Japan and in the Republic of Korea (South Korea), where national indicators and governance exist (Geng et al. 2019; Geng and Hengxin 2009).

(Zeng et al. 2020) have assessed the role of eco-industrial parks in China's green transformation for 33 development zones in relation to contributions to GDP, industrial value added, exports, water and energy consumption, CO₂ levels and sulphur emissions. They concluded that industrial parks have played a very important role in China's industrialisation, and that this structure has supported the decoupling of economic growth and energy and water consumption from the environmental impacts. However, improved environmental performance would require better access to finance and a higher priority by management.

Eco-industrial parks have been promoted in Ethiopia by the government and UNIDO, based on the expectation that they could help to boost the economy (UNIDO 2018). One of the success stories is an industrial park in Hawassa, a nation-level textile and garment industrial park with a 'zero emissions commitment' based on renewable energy and energy-efficient technologies. However, the concept of the industrial park, including feasible policies and institutional arrangements, is new to Ethiopia's regulatory processes, and this has created problems for management, knowledge and governance, hindering their fast implementation.

A number of business associations have developed strategies for sustainable development and climate change, including corporate social responsibility (CSR). International initiatives have included the promotion of CSR initiatives by international investors in low-income countries to support a broad range of development priorities, including social working conditions, eliminating child labour and climate change (Lamb et al. 2017). (Leventon et al. 2015) evaluated the role of mining industries in Zambia in supporting climate-compatible development and concluded that, although the industry

has played a positive role in avoiding migration and pressure on forest resources, there is a lack of coordination between government and industry initiatives.

It can be concluded that most of the mitigation options in industry considered in this section could have synergies with the SDGs, but also that some of the renewable-energy options could indicate some trade-offs in relation to land use, with implications for food- and water security and costs. Carbon capture and storage (CCS) could play an enabling role in the provision of reliable, sustainable and modern energy and could support decarbonisation, but it can also be costly (IEAGHG 2020; Mikunda et al. 2021). The provision of water for CCS can include both synergies and trade-offs with the SDGs due to recent progress in water-management technologies (Giannaris et al. 2020; IEAGHG 2020; Mikunda et al. 2021).

17.3.3.4 Cities, Infrastructure and Transportation

With 80% of the global population expected to be urban by 2050, cities will shape development paths for the foreseeable future (United Nations 2018). The challenge for many policymakers is to construct development paths that make cities clean, prosperous and liveable while mitigating climate change and building resilience to heatwaves, flooding and other climate risks. The IPCC SR1.5 report sees achieving these objectives as feasible: cities could potentially realise significant climate and sustainable-development benefits from shifting development paths (Wiktorowicz et al. 2018). This section assesses the synergies and trade-offs between meeting the SDGs and climate change mitigation, as well as providing a general overview of mitigation options in cities and of enabling factors, including city networks and plans for jointly addressing the SDGs and climate change mitigation.

Chapter 8 concludes that urban areas potentially offer several joint benefits between mitigation and the SDGs, and that since AR5, evidence of the co-benefits of urban mitigation continues to grow. In developing countries, a co-benefits approach that frames climate objectives alongside other development benefits arise increasingly being seen as an important concept justifying and driving climate change actions in developing countries (Sethi and Puppum De Oliveria 2018; Seto et al. 2016).

Evidence of the co-benefits of urban mitigation measures on human health has increased significantly since the IPCC AR5, especially through the use of health-impact assessments in cities like Geneva, where energy savings and cleaner energy-supply structures based on measures for urban planning, heating and transport have reduced CO₂, NO_x and PM₁₀ emissions and increased the opportunities for physical activity for the prevention of cardiovascular diseases (Diallo et al. 2016).

There is increasing evidence that climate-mitigation measures can lower health risks that are related to energy poverty, especially in vulnerable groups, such as the elderly (Monforti-Ferrario et al. 2019). Moreover, the use of urban forestry and green infrastructure as both a climate mitigation and an adaptation measure can reduce heat stress (Kim and Coseo 2019; Privitera and La Rosa 2017)

while removing air pollutants to improve air quality (Scholz et al. 2018; De la Sota et al. 2019) and enhancing well-being, including contributions to local development and possible reductions of inequalities (Lwasa et al. 2015). Other studies evidence the potential to reduce premature mortality by up to 7000 in 53 towns and cities, to create 93,000 net new jobs and lower global climate costs, as well as reduce personal energy costs based on road maps for renewable-energy transformations (Jacobson et al. 2018).

The co-benefits of energy-saving measures described by 146 signatories to a city climate network due to improved air quality have been quantified as 6596 avoided premature deaths (with a 95% confidence interval of 4356 to 8572 avoided premature deaths) and 68,476 years of life saved (with a 95% confidence interval of 45,403 and 89,358 years of life saved) (Monforti-Ferrario et al. 2019). Better air quality further reinforces the health co-benefits of climate-mitigation measures based on walking and cycling, since the evidence suggests that increased physical activity in urban outdoor settings with low levels of black carbon improves lung function (Laeremans et al. 2018). Chapter 9 shows that mitigation actions in buildings have multiple co-benefits resulting in substantial social and economic value beyond their direct impacts on reducing energy consumption and GHG emissions, thus contributing to the achievement of almost all the UN's SDGs. Most studies agree that the value of these multiple benefits is greater than the value of the energy savings, while their quantification and inclusion in decision-making processes will strengthen the adoption of ambitious reduction targets and improve coordination across policy areas.

There are several examples of cities that have developed plans for meeting both the SDGs and mitigation, which demonstrates the feasibility of meeting these objectives jointly. Quito, Ecuador, a city with large carbon footprints (Global Opportunity Explorer 2019) and climate vulnerabilities, has adopted low-carbon plans that aim to achieve the climate goals while introducing net-zero energy buildings and reducing water stress (Ordoñez et al. 2019; Marcotullio et al. 2018). Several cities in China, Indonesia and Japan have invested in green-city initiatives by means of green infrastructural investments, which is claimed to be a form of smart investment. Through this type of investment, economic growth and greenhouse gas (GHG) emissions reductions can be achieved in cities (Jupesta et al. 2016). Multi-level governance arrangements, public-private cooperation and robust urban-data platforms are among the factors enabling the pursuit of these objectives within countries (Corfee-Morlot et al. 2009; Gordon 2015; Creutzig et al. 2019; Yarime 2017).

In addition to the mostly domestic enablers listed previously, some cities have also benefited from working with international networks. The Global Covenant of Mayors for Climate & Energy (Covenant of Mayors 2019), the World Mayors Council on Climate Change, ECLEI, C40, and UNDRR (C40 Cities 2019; ECLEI 2019; UNDRR 2019) have provided targeted support, disseminated information and tools, and sponsored campaigns (Race to Zero) to motivate cities to embrace climate and sustainability objectives. Despite this support, it should be stressed that most cities are in the early stages of climate planning (Eisenack and Reckien 2013; Reckien et al. 2018; Climate-ADAPT 2019). Furthermore, in some cases city policymakers may

fail to highlight the synergies and trade-offs between climate and sustainable development or rebrand GHG-intensive practices as 'sustainable' in relevant plans (Tozer 2018).

With regard to city networks, Section 8.5 concludes that the importance of urban-scale policies for sustainability has increasingly been recognised by international organisations and national and regional governments. For example, in 2015, more than 150 national leaders adopted the UN's 2030 Sustainable Development Agenda, including stand-alone SDG 11 (sustainable cities and communities) (UN 2015 p. 14). The following year, 170 countries agreed to the UN New Urban Agenda (NUA), a central part of which is recognising the importance of national urban policies (NUPs) as a key to achieving national economic, social and environmental goals (United Nations 2015a 2017). Similarly, the Sendai Framework for Disaster Risk Reduction identifies the need to focus on unplanned and rapid urbanisation to reduce exposure and vulnerability to the risks of disasters (United Nations 2015b).

For many cities, a key to reorienting development paths will be investing in sustainable, low-carbon infrastructure. Because infrastructure has a long lifetime and influences everything from lifestyle choices to consumption patterns, decisions over an estimated USD90 trillion of infrastructure investment (from now to 2030) will be critical in order to avoid becoming locked-in to unsustainable paths (WRI 2016). This is particularly true in developing countries, where demands for new buildings, roads, energy and waste-management systems are already surging. To some extent, policies that accelerate building renovation rates, including voluntary programmes (Van der Heijden 2018), can support transitions down more sustainable paths (Kuramochi et al. 2018). Factoring climate and sustainable development considerations into policy tools that facilitate the quantitative emission performance standard (EPS) and the inclusion of climate and sustainable development benefits and risks in infrastructure assessments or risk-adjusted returns on investments in development banks could also prove useful (Rydge et al. 2015). Strong policy signals from the UNFCCC and from national climate policies and strategies (including NDCs) could facilitate uptake of the relevant policies and the use of these tools.

Infrastructural investments will also have wide-ranging implications for sustainable, low-carbon urban development, namely transport and mobility. To some extent, decision-making frameworks such as Avoid-Shift-Improve (ASI) could help make these patterns low carbon and sustainable (Dalkmann and Brannigan 2007; Wittneben et al. 2009). Mixed land-use planning and compact cities can not only help avoid emissions or shift travellers into cleaner modes (Cervero 2009), they can also improve air quality, reduce commuting times, enhance energy security and improve connectivity (Zusman et al. 2011; Pathak and Shukla 2016).

17.3.3.5 Mitigation-adaptation Relations

The section will consider the links between mitigation and adaptation options in the context of sustainable development and the associated synergies and trade-offs. Cross-cutting conclusions will be drawn based on Chapter 3 and the sectoral chapters of AR6 WGIII and

Chapter 18 of AR6 WGII. The focus will be on the following sectors: agriculture, food and land use; water-energy-food; industry and the circular economy; and urban areas.

IPCC AR6 WGII, concludes that coherent and integrated policy planning is needed in order to support integrated climate change adaptation and mitigation policies, and that this is a key component of climate-resilient development pathways. Section 4.5.2 assesses development pathways and the specific links between mitigation and adaptation, concluding that there can be co-benefits, and trade-offs, where mitigation implies maladaptation. However, adaptation can also be a prerequisite for mitigation. It is therefore concluded that making development pathways more sustainable can build the capacity for both mitigation and adaptation.

Climate actions, including climate change mitigation and adaptation, are highly scale-dependent, and solutions are very context-specific. Especially in developing countries, a strong link exists between sustainable development, vulnerability and climate risks, as limited economic, social and institutional resources often result in low adaptive capacities and high vulnerability. Similarly, the limitations in resources also constitute key elements weakening the capacity for climate change mitigation (Jakob et al. 2014). The change to climate-resilient societies requires transformational or systemic changes, which also have important implications for the suite of available sustainable-development pathways (Kates et al. 2012; Lemos et al. 2013). Thornton and Comberti (2017) point to the need for social-ecological transformations to take place if synergies between mitigation and adaptation are to be captured, based on the argument that incremental adaptation will not be sufficient when climate change impacts can be extreme or rapid and when deep decarbonisation simultaneously involves social change (Chapter 18 in AR6 WGII).

As discussed in AR6 WGII, Section 18.4, there are synergies and trade-offs between adaptation and sustainable development, as well as between mitigation and sustainable development, which is supported by comprehensive assessments such as that by Dovie (2019) and Sharifi (2020). Links between mitigation and adaptation options are identified in Chapter 18 in AR6 WGII, such as expected changes in energy demand due to climate change interacting with energy-system development and mitigation options, changes to agricultural production practices to manage the risks of potential changes in weather patterns affecting land-based emissions and mitigation strategies, or mitigation strategies that place additional demands on resources and markets. This increases the pressures on and costs of adaptation or ecosystem restoration linked to carbon sequestration and the benefits in terms of the resilience of natural and managed ecosystems, but it also could restrict mitigation options and increase costs. Chapter 3 of AR6 WGIII similarly concludes that the connectedness and coherence of actions to mitigate climate change could support the conservation and adaptation of ecosystems and meet the Sustainable Development Goals more widely.

Options to reduce agricultural demand (e.g., dietary change, reducing food waste) can have co-benefits for adaptation through reductions in the demand for land and water (Smith et al. 2019b). For example,

Grubler et al. (2018) show that stringent climate-mitigation pathways without reliance on BECCS can be achieved through efficiency improvements and reduced energy service and consumption levels in high-income countries.

Agriculture, food and land use is the sector where most climate policy options can simultaneously generate impacts on mitigation, adaptation and the SDGs (Locatelli et al. 2015; Kongsager et al. 2016). Bryan et al. (2013) identified a range of synergies and trade-offs across adaptation, mitigation and the SDGs in Kenya, given the diversity of its climatic and ecological conditions. Improved management of soil fertility and improved livestock-feeding practices could provide benefits to both climate change mitigation and adaptation, as well as increase income generation from farming. However, other improvements to agricultural management in Kenya, for example, soil water conservation, could only provide benefits across all three domains in some specific sub-regions.

Conservation agriculture can yield mitigation co-benefits through improved fertiliser use or the efficient use of machinery and fossil fuels (Harvey et al. 2014; Pradhan et al. 2018; Cui et al. 2019). Climate-smart agriculture (CSA) ties mitigation to adaptation through its three pillars of increased productivity, mitigation and adaptation (Lipper et al. 2014), although managing trade-offs among the three pillars requires care (Kongsager et al. 2016; Thornton and Comberti 2017; Soussana et al. 2019). Sustainable intensification also complements CSA (Campbell et al. 2014). Enhanced sustainable adaption can lead to effective emission-reduction benefits, such as climate-smart agricultural technologies (Nefzaoui et al. 2012; Poudel 2014) and ecosystem-based adaptation. (Berry, P et al. 2015; Geneletti and Zardo 2016; Warmenbol and Smith 2018) have shown how increases in livelihoods can contribute to climate change mitigation in Europe.

Agroforestry can sustain or increase food production in some systems and increase farmers' resilience to climate change (Jones et al. 2013). Some sustainable agricultural practices have trade-offs, and their implementation can have negative effects on adaptation or other ecosystem services. Agricultural practices can aid both mitigation and adaptation on the ground, but yields may be lower, so there may be a trade-off between resilience to climate change and efficiency. Interconnections within the global agricultural system may also lead to deforestation elsewhere (Erb et al. 2016). Implementation of sustainable agriculture can increase or decrease yields, depending on context (Pretty et al. 2006) (Chapter 4).

Land-based mitigation and adaptation will not only help reduce greenhouse gas (GHG) emissions in the AFOLU sector, but also help augment the sector's role as a carbon sink by increasing forest and tree cover through afforestation and agroforestry activities, and other eco-system-based approaches. Some of these options, however, can also have negative impacts on GHG emissions in the form of indirect impacts on land use (Córdova 2019) (for a more detailed discussion, see Chapter 7). If managed and regulated appropriately, the land use, land-use change and forestry (LULUCF) sector could play a key role in mitigation and be a key sector for emissions reductions beyond 2025 instead of contributing substantially to emissions reductions

beyond 2025 (Córdova et al. 2019; Keramidas et al. 2018). However, the large-scale deployment of intensive bioenergy plantations, including monocultures, replacing natural forests and subsistence farmlands are likely to have negative impacts on biodiversity and can threaten food and water security, as well as local livelihoods, partly by intensifying social conflicts, partly by reducing resilience (Díaz et al. 2019). Expansion on to abandoned or unused croplands and pastures nonetheless presents significant global potential, and will avoid the sustainability risks of expanding agriculture into natural vegetation (Næss et al. 2021).

Based on a literature review, (Berry, P et al. 2015) identified water-saving and irrigation techniques in agriculture as attractive adaptation options that have positive synergies with mitigation in increasing soil carbon, reducing energy consumption and reducing CH₄ emissions from intermittent rice-paddy irrigation. These measures could, however, reduce water flows in rivers and adversely affect wetlands and biodiversity. The study also concluded that afforestation could reduce peak water flows and increase carbon sequestration, but trade-offs could emerge in relation to the increased demand for water.

Fast-growing tree monocultures or biofuel crops may enhance carbon stocks but reduce downstream water availability and the availability of agricultural land (Harvey et al. 2014). Similarly, in some dry environments, agroforestry can increase competition with crops and pastureland, decreasing productivity and reducing the yields of catchment water (Schroback et al. 2011) (Chapter 7).

Hydropower dams are among the low-cost mitigation options, provided the cost of constructing the plant is taken into account, but they could have serious trade-offs in relation to key sustainable-development aspects, since in respect of water and land availability dams can have negative effects on ecosystems and livelihoods, thereby implying increased vulnerabilities. Section 17.3.3.2 on the water-energy-food nexus includes examples of trade-offs between the benefits of producing electricity from hydropower dams and the trade-offs with ecosystem services and using land for agriculture and livelihoods.

There are several potentially strong links between climate change adaptation in industry and climate change mitigation. Various supply chains can be affected by climate change, energy supply and water supply, and other resources can be disrupted by climate events. Adaptation measures can influence GHG emissions in their turn and thus mitigation because of the demand for basic materials, for example, as well as by influencing outdoor environments and labour productivity (Section 11.17.1.4).

Implementing adaptation options in industry can also imply increasing the demand for packaging materials such as plastics and for access to refrigeration. These are among the adaptation options that are dependent on temperature and storage possibilities, as well as being major sources of GHG emissions.

An increasing number of cities are becoming involved in voluntary actions and networks aimed at drawing up integrated plans for sustainable development and climate change mitigation and adaptation, including cities in both high- and low-income countries

around the world. (Grafakos et al. 2019; Sanchez Rodriguez et al. 2018) concluded that cities are an obvious place for the development of plans that can capture several synergies between sustainable development and climate-resilient pathways. (Kim and Grafakos 2019; Landauer et al. 2019) similarly concluded that cities are an obvious platform for the development of integrated planning efforts because of the scale of policies and actions, which could potentially match the different policy domains. (Kim and Grafakos 2019) assessed the level of integration of mitigation and adaptation in urban climate change plans across 44 major Latin American cities, concluding that the integration of climate change mitigation and adaption plans was very weak in about half the cities and that limited donor finance was a main barrier. The authors also mention barriers in relation to governance and the weakness or lack of legal frameworks. The integration of SDGs with adaptation could help increase the willingness of politicians to implement climate actions, as well as provide stronger arguments for investing the required resources (Sanchez Rodriguez et al. 2018).

The local integration of planning and policy implementation practices was also examined by (Newell et al. 2018) in a study of 11 Canadian communities. It was concluded that, in order to put plans into practice, a deeper understanding needs to be established of the potential synergies and trade-offs between sustainable development and climate change mitigation and adaptation. A model was applied to the evaluation of key impacts, including energy innovation, transportation, the greening of cities and city life. The impact assessment came to the conclusion that multiple benefits, costs and conflicting areas could be involved, and that bringing a broad range of stakeholders into policy implementation was therefore to be recommended.

There are several links between mitigation and adaptation options in the building sector, as pointed out in Chapter 9. Adaptation can increase energy consumption and associated GHG emissions (Kalvelage et al. 2013; Campagnolo and Davide 2019), for example, in relation to the demand for energy to meet indoor thermal comfort requirements in a future warmer climate (de Wilde and Coley 2012; Li and Yao 2012; Clarke et al. 2018). Mitigation alternatives using passive approaches may increase resilience to the impacts of climate change on thermal comfort and could reduce cooling needs (Wan et al. 2012; Andrić et al. 2019). However, climate change may reduce their effectiveness (Ürge-Vorsatz et al. 2014).

Mitigation and the co-benefits of adaptation in urban areas in relation to air quality, health, green jobs and equality issues are dealt with in Section 8.2, where it is concluded that most mitigation options will have positive impacts on adaptation, with the exception of compact cities, with trade-offs between mitigation and adaptation. This is because decreasing urban sprawl can increase the risks of flooding and heat stress. Detailed mapping between mitigation and adaptation in urban areas shows that there are many, very close interactions between the two policy domains and that coordinated governance across sectors is therefore called for.

Rebuilding and refurbishment after climate hazards can increase energy consumption and GHG emissions in the construction and

building materials sectors, as it could make the existing building stock more climate-resilient (Hallegatte 2009; de Wilde and Coley 2012; Pyke et al. 2012) and thus also support implementation of the Sendai Framework on Disaster Risk Reduction (United Nations 2015b). Climate change in the form of extremely high temperatures, intense rainfall leading to flooding, more intense winds and/or storms and sea level rises (SLRs) can seriously impact transport infrastructure, including the operations and mobility of road, rail, shipping and aviation; Chapter 10 assesses the impacts on subsectors within transportation. At the same time, these sectors are major targets for GHG mitigation options, and many countries are currently examining what to do in terms of combined mitigation-adaptation efforts, using the need to mitigate climate change through transport-related GHG emissions reductions and pollutants as the basis for adaptation action (Thornbush et al. 2013; Wang and Chen 2019). For example, urban sprawl indirectly affects climate processes, increasing emissions and vulnerability, which worsens the ability to adapt (Congedo and Munafo 2014). Hence greater use of rail by passengers and freight will reduce the pressures on the roads, while having less urban sprawl will reduce the impacts on new infrastructure, often in more vulnerable areas (IPCC 2019; Newman et al. 2017).

Despite many links between mitigation and adaptation options, including synergies and trade-offs, Chapter 13 concludes that there are few frameworks for integrated policy implementation. One review of climate legislation in Europe found a lack of coordination between mitigation and adaptation, their implementation varying according to different national circumstances (Nachmany et al. 2015).

In developing and least-developed countries (LDCs), there are many examples of climate policies in the NDCs that have been drawn up in the context of sustainable development and that cover both mitigation and adaptation (Beg 2002; Duguma et al. 2014) (Chapter 13). However, there are many barriers to joint policy implementation. Despite the emphasis on both mitigation and adaptation policies, there is very limited literature on how to design and implement integrated policies (Di Gregorio et al. 2017; Shaw et al. 2014). For example, the links within the water-energy-food nexus require coordination among sectoral institutions and capacity-building in innovative frameworks linking science, practice and policy at multiple levels (Cook and Chu 2018; Nakano 2017; Shaw et al. 2014).

Another challenge is the shortage of financial, technical and human resources for implementing joint adaptation and mitigation policies (Antwi-Agyei et al. 2018b; Chu 2018; David and Venkatachalam 2019; Kedia 2016; Satterthwaite 2017). Several studies have stressed that the lack of finance for integrating policy implementation between sustainable development and climate change mitigation and adaptation may constitute barriers to the implementation of adaptation projects to protect least-developed countries (LDCs) with many vulnerabilities.

(Locatelli et al. 2016) come to similar conclusions regarding finance based on interviews with multilateral development banks, green funds and government organisations in respect of the agricultural and forestry sectors. International climate finance has been totally dominated by mitigation projects. Those who were interviewed

were asked about their willingness to change this balance and to commit more resources to projects that address both climate change mitigation and adaptation. More than two thirds of those interviewed, however, raised concerns that integrated projects could be too complicated and that a greater alignment of financial models across different policy domains could entail greater financial risks. Another barrier mentioned in respect of finance was that mitigation projects were primarily aimed at GHG emissions reductions, while adaptation projects had more national benefits and were also more suitable for community development and promoting equality and fairness. In an assessment of 201 projects in the forestry and agricultural sectors in the tropics, (Kongsager et al. 2016), found that a majority of the projects contributed to both adaptation and mitigation or at least had the potential to do so, despite the separation between these two objectives by international and national institutions.

17.3.3.6 Cross-sectoral Digitalisation

In this section, the potential role of digitalisation as a facilitator of a fast transition to sustainable development and low-emission pathways is assessed based on sectoral examples. The contributions of digital technology could contribute to efficiency improvements, cross-sectoral coordination, including new IT services, and decreasing resource use, implying several synergies with the SDGs, as well as trade-offs, for example, in relation to reduced employment, increasing energy demand and the increasing demand for services, possibly increasing GHG emissions.

The COVID-19 pandemic caused radical temporary breaks with past energy-use trends. How post-pandemic recovery will impact on the longer-term energy transition is unclear. Recovering from the pandemic with energy-efficient practices embedded in new patterns of travel, work, consumption and production reduces climate mitigation challenges (Kikstra et al. 2021). The potential of digital contact tracing to slow the spread of a virus had been quietly explored for over a decade before the COVID-19 pandemic thrust the technology into the spotlight (Cebrian 2021). The COVID-19 crisis is among the most disruptive events in recent decades and has had consequences for consumer behaviour. During the lockdowns in most countries, consumers have turned to online shopping for food products, personal hygiene and disinfection (Cruz-Cárdenas et al. 2021), making society more digitally literate.

The cost of new services provided by digitalisation can be high, and this could imply barriers for low-income countries in joining new global information-sharing systems and markets. Altogether this implies that any assessment of the contribution of digitalisation to support the SDGs and low-carbon pathways will only be able to provide very context-specific results. Digital technologies could potentially disrupt production processes in nearly every sector of the economy. However, as an emerging area experiencing the rapid penetration of many sectors, there could be a window of opportunity for integrating sustainable development and low-emission pathways. (IIASA 2020) concludes that the digital revolution is characterised by many innovative technologies, which can create both synergies and trade-offs with the SDGs (IIASA 2020).

Digital technologies could potentially disrupt production processes in nearly every sector of the economy. However, as an emerging area experiencing the rapid penetration of many sectors, there could be a window of opportunity for integrating sustainable development and low-emission pathways. TWI2050 (2020) concludes that the digital revolution is characterised by many innovative technologies, which can create both synergies and trade-offs with the SDGs (IIASA 2020).

WBSD (2019) has assessed the potential of communication technologies (ICT) to contribute to the transition to a global low-carbon economy in the energy, transportation, building, industry, and other sectors. The potential is estimated to be around 15% CO₂-eq emissions reductions in 2020 compared with a business-as-usual scenario. A range of ICT solutions have been highlighted, including smart motors and industrial process-management in industry, traffic-flow management, efficient engines for transport, smart logistics and smart-energy systems.

The TWI2050 2019 report (IIASA 2019) assessed both the positive and negative impacts of digitalisation in the context of sustainable development. It found that efficiency improvements, reduced resource consumption and new services can support the SDGs, but also that there were challenges, including in relation to equality, facing the least-developed and developing countries because of their low level of access to technologies. The necessary preconditions for successful digital transformation include prosperity, social inclusion, environmental sustainability, protection of jobs and good governance of sustainability transitions. One negative impact of digitalisation could be the rebound effects, where easier access to services could increase demand and with it GHG emissions. Digitalisation in the manufacturing sector could also provide a comparative advantage to developed countries due to the falling importance of labour costs, while the barriers to emerging economies seeking to enter global markets could accordingly be increased.

In respect of governance, (Krishnan et al. 2020) point out that the creation of synergies between sustainable development and low-emission urbanisation based on digitalisation could face barriers in the form of inadequate knowledge of structures and value creation through ecosystems that would need to be addressed by means of smart digitalising, requiring organisational measures to support transformation processes.

Urban areas are one of the main arenas for new digital solutions due to rapid urbanisation rates and high concentrations of settlements, businesses and supply systems, which offer great potential for large-scale digital systems. The emergence of smart cities has supported the uptake of smart integrated energy, transportation, water and waste-management systems, while synergies have been created in terms of more flexible and efficient systems. In its 2018 Policy and Action document, the Japanese Business Federation (Keidanren) launched Society 5.0, which includes plans for smart-city development (Carras and Yuko 2019; Narvaez Rojas et al. 2021). To achieve smart cities, Society 5.0 aimed to facilitate diverse lifestyles and business success, while the quality of life offered by these options will be enhanced. It also aims to offer high-standard medical and educational services.

Autonomous vehicles will be available and integrated with smart-grid systems in order to facilitate mobility and flexibility in energy supply with a high share of renewable energy.

Chapter 6 of this report on 'Energy Systems' points out that there are many smart-energy options with the potential to support sustainable development by facilitating the integration of high shares of fluctuating renewable energy in electricity systems, potentially storing energy in electric vehicle (EV) batteries or fuel cells, and applying load shifting by varying prices over time. It is concluded that very large efficiency gains are expected to emerge from digitalisation in the energy sector (Figure 6.18).

Section 9.9.2 in Chapter 9 concludes that the improved energy efficiency and falling costs in the building sector that could result from digitalisation could have rebound effects in increasing both energy consumption and comfort levels. Increasing GHG emissions could be the result, but if low-income consumers are given faster access to affordable energy, this could agree with the SDGs, making it desirable to integrate policies targeting mitigation.

Section 10.1.2 in Chapter 10 discusses how the sharing economy, which, for example, could be facilitated by ICT platforms, could influence both mitigation and the SDGs. On the one hand, sharing has the potential to save transport emissions, especially if EVs are supplied with decarbonised grid electricity. However, an increase in transport emissions could result from this if increasing demand and higher comfort levels are facilitated, for example, by making access to EVs relatively easy compared with mass transit. Another possible trade-off is that the supply of public transport services would be limited to the elderly and other user groups.

Green innovation in agriculture is another emerging area in which digitalisation is making huge progress. From the perspective of water provision, weather data can be used to predict rain amounts so that farmers can better manage the application of farm chemicals to minimise polluting aquifers and surface-water systems used for drinking water. Meanwhile, smart meters, on-site and remote sensors and satellite data connected to mobile devices allow real-time monitoring of crop-water and optimal irrigation requirements. On the supply side, remote tele-control systems and efficient irrigation technologies enable farmers to control and optimise the quantity and timing of water applications, while minimising the energy-consumption trade-offs of pressurised irrigation in both rural and urban agricultural contexts (Germer et al. 2011; Ruiz-Garcia et al. 2009).

Technology-driven precision agriculture, which combines geomorphology, satellite imagery, global positioning and smart sensors, enables enormous increases in efficiency and productivity. Taken together, these technologies provide farmers with a decision-support system in real time for the whole farm. Arguably, the world could feed the projected rise in population without radical changes to current agricultural practices if food waste can be minimised or eliminated. Digital technologies will contribute to minimising these losses through increased efficiencies in supply chains, better shipping and transit systems, and improved refrigeration.

In conclusion, in most cases digitalisation options may have both positive synergistic impacts on mitigation and the SDGs and some negative trade-offs. Energy-sector options are assessed primarily as having synergies, while some digitalisation options in transport could increase the demand for emission-intensive modes of transport. Digital platforms for the sharing economy could have both positive and negative impacts depending on the goods and services that are actually exchanged (Cross-Chapter Box 6 in Chapter 7). Options related to agriculture and the water-energy-food nexus (WEFN) could help manage resources more efficiently across sectors, which could create synergies. Digitalisation can also raise a number of ethical challenges according to (Clark et al. 2019). Wider public discussion of internet-based activities was accordingly recommended, including topics such as the negotiation of online consent and the use of data for which consent has not been obtained.

17.3.3.7 Cross-sectoral Overview of Synergies and Trade-offs Between Climate Change Mitigation and the SDGs

Based on a qualitative assessment in the sectoral Chapters 6, 7, 8, 9, 10, and 11, Figure 17.1 below provides an overview of the most likely links between sectoral mitigation options and SDGs in terms of synergies and trade-offs. The general overview provided in the figure is supplemented by specific sector-by-sector comments on how the synergies and trade-offs mapped depend on the scale of implementation and the overall development context of places where the mitigation options are implemented. For some mitigation options these scaling and context-specific issues imply that there can be both synergies and trade-offs in relation to specific SDGs. In addition to the information provided in Figure 17.1, Supplementary Material Table 17.SM.1 includes the detailed background material provided by the sectoral chapters in terms of qualitative information for each of the synergies and trade-offs mapped.

The assessment of synergies and trade-offs presented in Figure 17.1 depends on the underlying literature assessed by the sectoral chapters. In cases where no information about the links between specific mitigation options and SDGs are indicated, this does not imply that there are no links, but rather that the links have not been assessed by the literature.

Most of the energy-sector options are assessed as having synergies with several SDGs, but there could be mixed synergies and trade-offs between SDG 2 (zero hunger) for wind and solar energy, and for hydropower due to land-use conflicts and fishery damage. Offshore wind could also have both synergies and trade-offs with SDG 14 (life below water) dependent on scale and implementation site, and it is emphasised that land-use should be coordinated with biodiversity concerns. Both wind and solar energy are assessed as having trade-offs with SDG 12 (responsible production and consumption) due to significant material consumption and disposal needs.

Geothermal energy is assessed as having synergies with SDG 1 (no poverty) due to energy access, and mixed synergies and trade-offs in relation to SDG 3 (good health and well-being) due to reduced air pollution, but with some risks in relation to water pollution, and in relation to SDG 6 (clean water and sanitation), if it is not

well managed. Nuclear power is assessed as having synergies with SDG 3 (good health and well-being) due to reduced air pollution, but potential trade-offs in relation to SDG 6 (clean water and sanitation) due to high water consumption, and water consumption issues are also possible in relation to many of the other mitigation options in the energy sector. Synergies are identified in relation to SDG 12 (responsible production and consumption) for nuclear power due to low material consumption. CCUS has been assessed as having trade-offs in relation to SDG 1 (no poverty) due to high costs and SDG 6 (clean water and sanitation) due to high water consumption. Synergies are related to SDG 3 (good health and well-being), and to SDG 9 (industry, innovation and infrastructure) due to the facilitation of decarbonisation of industrial processes. Both synergies and trade-offs could arrive in relation to SDG 12 (responsible production and consumption), since some rare chemicals and other inputs could in some cases be used with large-scale applications.

Bioenergy use as a fuel is assessed as one of the energy-sector mitigation options with most synergies and trade-offs with the SDGs. There could be synergies with SDG 1 (no poverty), with SDG 8 (decent work and economic growth) and SDG 9 (industry, innovation and infrastructure). This option, however, if combined with CCS, can be expensive and can compromise SDG 1 (no poverty) due to the high costs involved.

Agriculture, forestry and other land use (AFOLU) mitigation options are very closely linked to the SDGs and offer both synergies and trade-offs, which in many cases are highly dependent on the scale of implementation. All the mitigation options included in Figure 17.1 are assessed as potentially having synergies with SDG 1 (no poverty), but trade-offs could also happen if large areas are used for biocrops and taken away from other activities, thus causing poverty, as well as in relation to food costs if healthier diets are made more expensive. In relation to SDG 2 (zero hunger), most of the mitigation options are assessed as being associated with both synergies and trade-offs. Trade-offs are particularly a risk with large-scale applications of afforestation projects, bioenergy crops and other land-hungry activities, which can crowd out food production.

SDG 3 (good health and well-being) can be supported by many mitigation options in the agriculture, forestry and food sectors, primarily due to the reduced environmental impacts, and the same is the case with SDG 14 (life below water) due to decreased nutrient loads, and SDG 15 (life on land) due to increased biodiversity, with the caveat however, that SDGs 14 and 15 could have both synergies and trade-offs dependent on land use. It is considered that there could be both synergies and trade-offs in relation to SDG 8 (decent work and economic growth) due to competition over land use related to the mitigation options reducing deforestation and reforestation and restoration, and the same is the case in relation to SDG 7 (affordable and clean energy) depending on the economic outcome of the mitigation options. Similarly, the mitigation option of reduced CH₄ and N₂O emissions from agriculture are assessed as having mixed impacts on SDG 8 (decent work and economic growth), and SDG 9 (industry, innovation and infrastructure) depending on innovative food production. The mitigation options of reforestation and forest management are assessed as having mixed impacts on

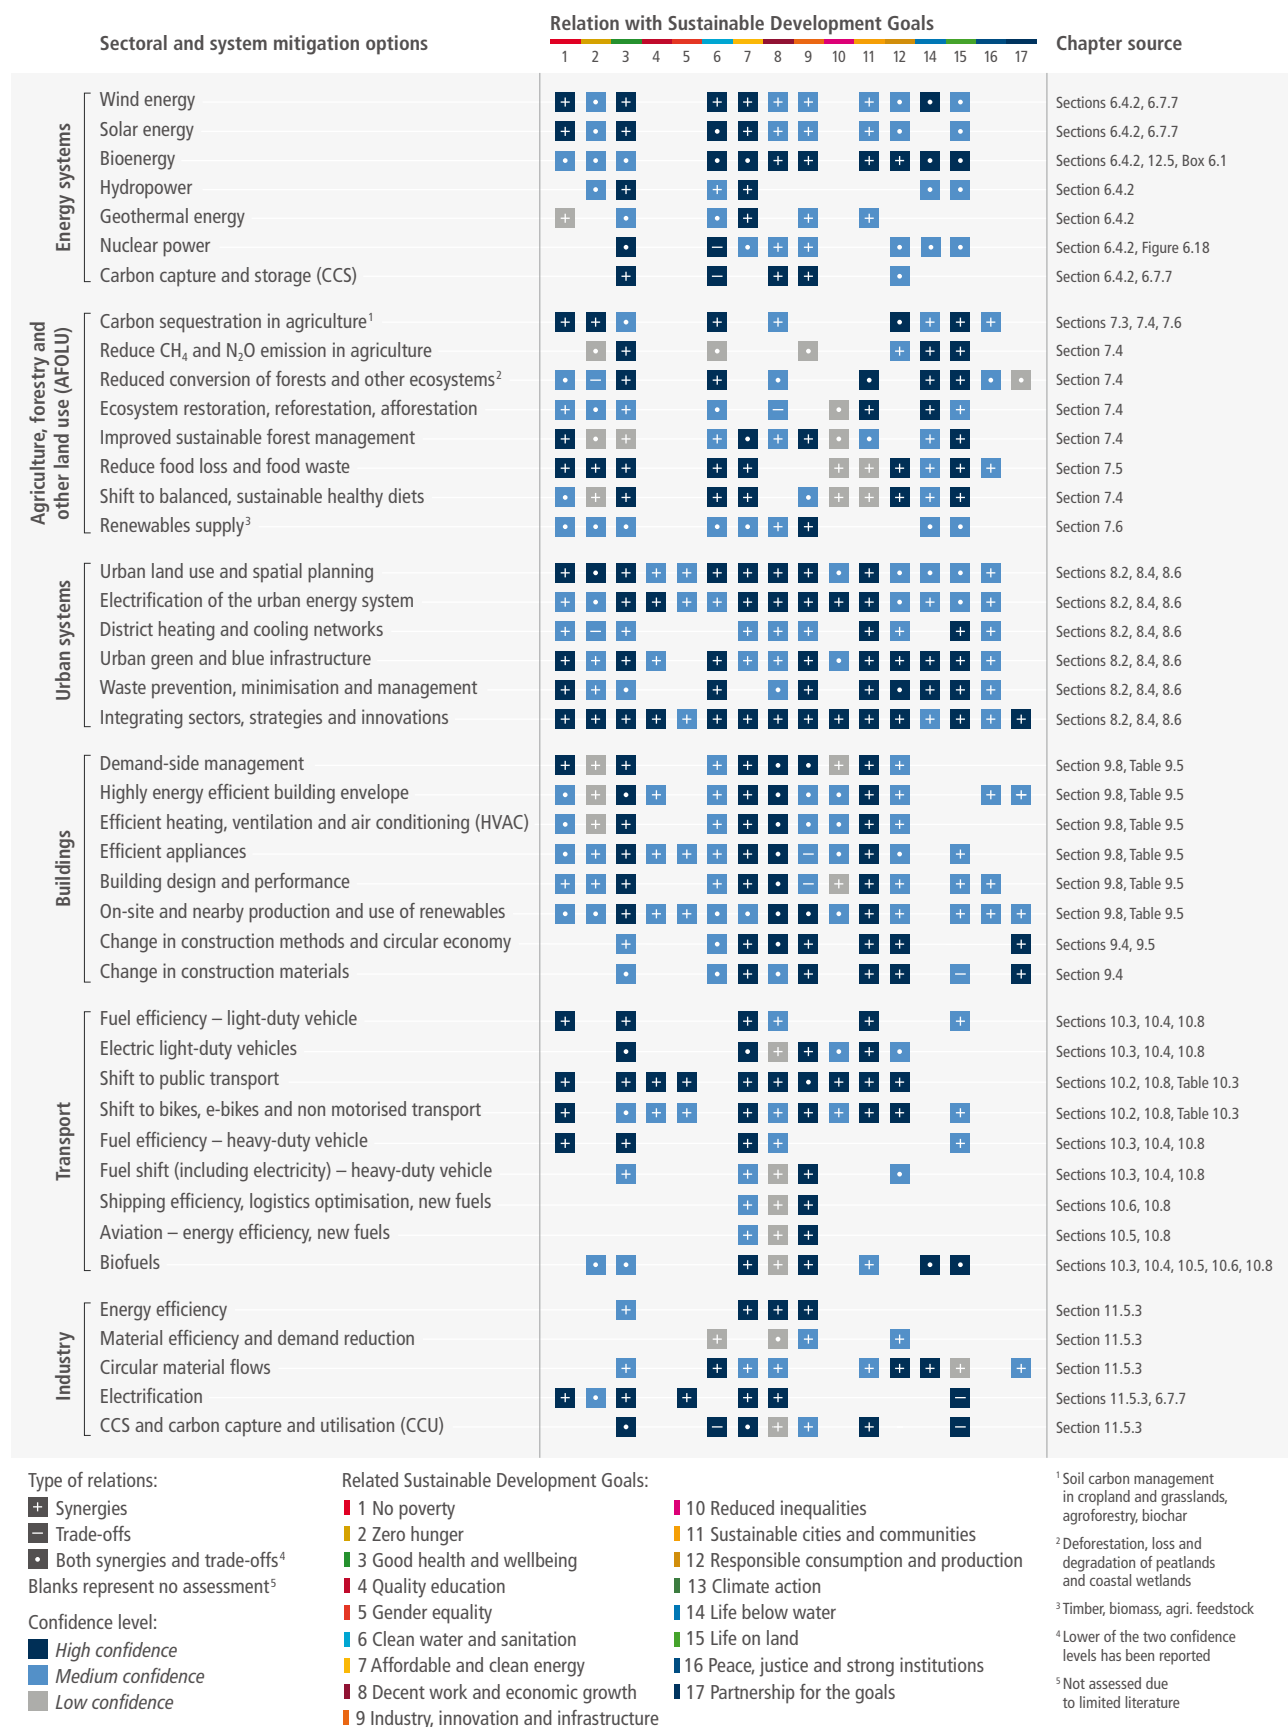

Figure 17.1 | Trade-offs and synergies between sectoral mitigation options and the Sustainable Development Goals (SDGs).

SDG 10 (reduced inequalities) depending on the involvement of local communities in projects. The assessment emphasises that the synergies and trade-offs of the mitigation options with the SDGs in this sector are very context- and scale-dependent, depending on how measures are carried out, for example, in relation to the enhanced production of renewables needed to replace fossil fuel-based products. If done on a massive scale and not adapted to local circumstances, there are adverse implications for food security, livelihoods and biodiversity.

All the urban mitigation options that have been assessed are considered to have synergies with the SDGs, and in a few cases both synergies and trade-offs are identified. In general, many links between mitigation options in the urban area and the SDGs have been identified in the literature. Urban land use and spatial planning, for example, can support SDG 1 (no poverty), and can also reduce vulnerability to climate change if integrated planning is undertaken, while access to food (SDG 2: zero hunger), and water (SDG 6: clean water and sanitation) can also be achieved if supported by integrated planning. Electrification, district heating, and green-and-blue infrastructure in urban areas are expected to have synergies with all the SDGs addressed by the reviewed studies.

Mitigation options like waste-prevention minimisation and management are also assessed as having many synergies with the SDGs, but trade-offs could depend on the application of air-pollution control technologies, and on the character of informal waste-recycling activities. The impacts of the possible synergies and/or trade-offs with the SDGs will change according to the specific urban context. Synergies and/or trade-offs may be more significant in certain contexts than others. Regarding the SDGs, urban mitigation can support shifting pathways of urbanisation towards sustainability. The feasibility of urban mitigation options is also malleable and can increase with more enablers. Strengthened institutional capacity that also supports the scale and coordination of the mitigation options can increase the synergies between urban mitigation options and the SDGs.

As for the urban mitigation options, the reviewed building-sector studies reveal a lot of links between mitigation and the SDGs. Highly efficient building envelopes are expected to have synergies with the SDGs in all cases except those with potential trade-offs in relation to SDG 10 (reduced inequalities). Many SDG synergies are also identified for the building design and performance, heating, ventilation and air conditioning, and efficient appliances mitigation options. However, some trade-offs could appear in relation to SDG 8 (decent work and economic growth) due to macroeconomic impacts of reduced energy consumption, decreasing prices and stranded investments. Similar issues related to the economic impacts of reduced energy demand are also highlighted for all the other mitigation options, including for the building sector. In relation to construction materials and the circular economy, some trade-offs have been identified in relation to SDG 6 (clean water and sanitation) and SDG 15 (life on land) related to the use of bio-based materials.

Consideration of the building sector highlights important context-specific issues related to synergies and trade-offs between mitigation

options and SDGs such as the economic impacts (synergies and trade-offs) associated with reduced energy demand, resulting in lower energy prices, energy-efficiency investments, the fostering of innovation and improvements in labour productivity. Furthermore, the distributional costs of some mitigation policies may hinder the implementation of these measures. In this case, appropriate access policies should be designed to shield poor households efficiently from the burden of carbon taxation. Under real-world conditions, improved cookstoves have shown smaller, and in many cases limited, long-term health and environmental impacts than expected, as the households use these stoves irregularly and inappropriately, and fail to maintain them, so that their usage declines over time. Specific distributional issues are highlighted in relation to various cookstove programmes.

The mitigation options in the transportation sector are assessed as having synergies with SDG 1 (no poverty) and SDG 3 (good health and well-being) due to reduced environmental pollution, with exceptions in relation to pollution from biofuels and the risks of traffic accidents. Trade-offs are also mentioned in relation SDG 2 (zero hunger) where the production of biofuels takes land away from food production. Synergies are assessed in relation to SDG 7 (affordable and clean energy), SDG 8 (decent work and economic growth) and SDG 9 (industry, innovation and infrastructure). It is emphasised that some mitigation options, like the increased penetration of electric vehicles, require innovative business models, and that digitalisation and automatic vehicles will support the socio-economic structures that impede adoption of EVs and the urban structures that enable reduced car dependence. In conclusion, there is a need for investments in infrastructure that can support alternative fuels for light-duty vehicles (LDVs). The large-scale electrification of LDVs requires the expansion of low-carbon power systems, while charging or battery-swapping infrastructure is needed for some segments.

The mitigation options in the industrial sector have been assessed primarily as having synergies with meeting the SDGs. Several options, including energy efficiency, material recycling and electrification, are assessed as being able to create increased employment and business opportunities related to SDG 8 (decent work and economic growth), but material-efficiency improvements could reduce tax revenues. Electrification is assessed as having many synergies with SDGs, such as supporting SDG 1 (no poverty), SDG 2 (zero hunger), and SDG 3 (good health and well-being). CCS applied in industry is assessed as having synergies in terms of the control of non-CO₂ pollutants (such as sulphur dioxide), but increases in non-CO₂ pollutants (such as particulate matter, nitrogen oxide and ammonia). The conclusion is that 15–25% additional energy will be required by CCS technologies compared with conventional plants, implying that production costs could increase significantly. For the industrial sector in general, it is concluded that the balance between synergies and trade-offs between mitigation options and SDGs in industry depends on technology and the scale of the sharing of co-benefits across regions, as well as on the sharing of benefits in business models over whole value chains.

Thus, a number of cross-sectoral conclusions on synergies and trade-offs between mitigation options and the SDGs appear from the overview provided in Figure 17.1. There are many synergies in all sectors between mitigation options and the SDGs, and in a few

cases there are also significant trade-offs that it is very important to address, since they can compromise major SDGs including SDG 1 (no poverty), SDG 2 (zero hunger), and in some cases SDG 14 (life below water) and SDG 15 (life on land). In particular, mitigation options in relation to land use, such as afforestation and reforestation and bioenergy crops, can in some cases imply trade-offs with access to food and local sharing of benefits, but synergies can also exist if proper land management and cross-sectoral policies take sustainable land use into account. The impacts and trade-offs for this sector are highly scale- and context-dependent, so the final outcome of mitigation policies should be considered in detail.

The urban systems and transportation could potentially achieve many synergies between mitigation policies and the SDGs, but integrated planning and infrastructure management are critical to avoiding trade-offs. Similarly, the buildings sector and industry have identified many potential synergies between mitigation options and the SDGs, but that raises issues related to the costs of new technologies, and in relation to households and buildings, important equity issues are emerging in relation to the ability of low-income groups to afford the introduction of new technologies. Altogether these cross-sectoral conclusions call for a need to support policies that aid coordination between different sectoral domains and that include context-specific assessments of the sharing of benefits and costs related to the implementation of mitigation options.

17.4 Key Barriers and Enablers of the Transition: Synthesising Results

This section provides a deep and broad synthesis of theory (Section 17.2) and evidence (Section 17.3) in order to identify the conditions that either enable or inhibit transitions to sustainable low-carbon futures. Following the literature on sustainability transitions (Cross-Chapter Box 12 in Chapter 16), the section finds that there is rarely any one single factor promoting or preventing such transitions. Rather, marked departures from business as usual typically involve several factors, including technological innovations, shifts in markets, concerted efforts by scientists and civil-society organisations to raise awareness of the costs of continued emissions, social movements, policies and governance arrangements, and changes in belief systems and values.

All of this comes together in a co-evolutionary process that has unfolded globally, internationally and locally over several decades (Hansen and Nygaard 2014; Rogge et al. 2017; Sorman et al. 2020), and that may be guided or facilitated by interventions that target leverage points in the underlying development path (Burch and Di Bella 2021; Leventon et al. 2021). While transitions necessarily follow context-specific trajectories, more general lessons can be drawn by comparing the empirical details with both system-level and narrower explanations of change.

Sections 17.2 and 17.3 show that transitions often face multiple barriers, including infrastructure lock-in, behavioural, cultural and institutional inertia (Markard et al. 2020), trade-offs between transitions and other social or political priorities (Chu 2016), cost and a reliable (and growing) supply of renewable-energy technologies

and constituent materials (García-Olivares et al. 2018). Transitions away from fossil fuels and toward renewable energy-based systems, for instance, will require significant land-use decisions to avoid negative trade-offs with biodiversity and food security (Capellán-Pérez et al. 2017). Previous sections underline a related need to move beyond focusing on 'rational' assessments of the costs and benefits of policies and technologies to involve people at all levels in order to overcome these multiple barriers. A transition to a lower carbon system is unlikely to happen even if models find it technically feasible and cost-effective. Rather, achieving a transition requires breaking locked-in high-carbon technological trajectories, path dependencies and resistance to change from the industries and actors that are benefiting from the current system (Rogge et al. 2017). Lock-in effects may be weaker in sectors and policy areas where fewer technologies exist, potentially opening the door to innovations that embed the climate in broader sustainability objectives (e.g., technologies and innovations that support the integration of food, water and energy goals). Such effects may still happen when there are significant information asymmetries and high-cost barriers to action, as can occur when working across multiple climate and development-related sectors (Kemp and Never 2017).

However, the same conditions that may serve to impede a transition (i.e., organisational structure, behaviour, technological lock-in) can also be 'flipped' to enable it (Burch 2010; Lee et al. 2017), while the framing of policies that are relevant to the sustainable development agenda can also create a stronger basis and stronger policy support. The technological developments and broader cultural changes that may generate new social demands on infrastructure to contribute to sustainable development will involve a process of social learning and awareness building (Naber et al. 2017; Sengers et al. 2019). However, it is also important to note that strong shocks to these systems, including accelerated climate change impacts, economic crises and political changes, may provide crucial openings for accelerated transitions to sustainable systems through fundamental institutional changes (Broto et al. 2014). The global COVID-19 pandemic is one such shock that has sparked widespread conversations about recovery that is fundamentally more sustainable, equitable and resilient (McNeely and Munasinghe 2021). Key enabling conditions appear to be individual and collective actions, including leadership and education; financial, material, social and technical drivers that foster innovation; robust national and regional innovation systems that enhance technological diffusion (Wieczorek 2018); supportive policy and governance dynamics at multiple levels that permit both agility and coherence (Göpel et al. 2016); measures to recognise and address the challenges to equality inherent in the transition; and long-range, holistic planning that explicitly seeks synergies between climate change and sustainable development while avoiding trade-offs. The sections that follow seek to assess and integrate these key categories of the barriers to and enablers of an accelerated transition to sustainable development pathways.

17.4.1 Behavioural and Lifestyle Changes

Transitions toward more sustainable development pathways are both an individual and a collective challenge, requiring an examination

of the role of values, attitudes, beliefs and structures that shape behaviour, and of the dynamics of social movements and education at the local community, regional and global levels. Labelling the carbon included in products, for example, could help the decision-making process and increase awareness and knowledge. Individual action suggests aggregated but uncoordinated actions taken by individuals, whereas collective sustainability actions involve coordination, a process of participation and governance that may ensure more efficient, equitable and effective outcomes. There is evidence that the behaviour of individuals and households are part of a more encompassing collective action (Section 5.4.1).

Indeed, individual actions are necessary but insufficient to deliver transformative mitigation, and it is suggested that this be coupled with collective actions to accelerate the transition to sustainable development (Dugast et al. 2019). Actors with conflicting interests will compete to frame mitigation technologies that either 'build or erode' the legitimacy of the technology, contested framing sites that can occur between incumbent and emerging actors or between actors in new but competing spaces (Rosenbloom et al. 2016). How narratives are built around desired development pathways and specific emerging technologies, as well as how local values are integrated into visions of the future, have relevance for how these experiments are managed and enabled to expand (Horcea-Milcu et al. 2020; Lam et al. 2020).

17.4.1.1 Social Movements and Education

Sustainable development and deep decarbonisation will involve people and communities being connected locally through various means – including globally via the internet and digital technologies (Bradbury 2015; Scharmer 2018; Scharmer, C, Kaufer 2015) – in ways that form social fields that allow sustainability to unfold (Gillard et al. 2016), and that prompt other shifts in thinking and behaviour that are consistent with the 1.5°C goal (O'Brien 2018; Veciana and Ottmar 2018). Indeed, social movements serve to develop collective identities, foster collective learning and accelerate collective action ranging from energy justice (Campos and Marín-González 2020) (Section 17.4.5) to restricting fossil fuel extraction and supply (Piggot 2018). This does not apply only to adults: as seen in the 'Fridays for Future' marches, the young are also involving themselves politically (Peterson et al. 2019). Many initiatives have started with these marches, including 'science for future' and new forms of sustainability science (Shrivastava et al. 2020).

It was Theory-U (Scharmer 2018), building on the work of scholars such as Schein, Lewin and Senge) that inspired a so-called 'massive open online course' (MOOC) jointly initiated by the Bhutan Happiness Institute and German Technical Assistance (GIZ) in 2015, since when it has been developed further and adapted to transform business, society and self as one example of how social movements can go together with science and education. It brings together people from different professions, cultures and continents in shared discussions and practices of sustainability. It also included marginalised communities and is shifting towards more sustainable lifestyles in all sectors (Nikas et al. 2020), including climate action.

Moreover, approaches like the 'Art of Hosting' (Sandfort and Quick 2015) and qualitative research methods such as storytelling and first-person research, as well as second-person inquiries, for example (Scharmer, C, Kaufer 2015; Trullen and Torbert 2004; Varela 1999), have been employed to bridge differences in cultures and sciences, as well as to forge connections between those working on climate change and sustainable development. Likewise, experiential tools, simulations and role-playing games have been shown to increase knowledge of the causes and consequences of climate change, the sense of urgency around action and the desire to pursue further learning (Ahamer 2013; Eisenack and Reckien 2013; Hallinger et al. 2020; Rooney-Varga et al. 2020).

The results from these research communities reveal how experiential learning takes place and how it encourages bonding between people, society and nature. This can be achieved by going jointly and consciously into nature (Gioacchino 2019), by creating spaces for intensive-dialogue sessions with colleagues (Goldman-Schuyler et al. 2017) and forming, for example, a very practical u.lab hub, which involves following the MIT-u.lab course with a local community and is accompanied scientifically (Pomeroy and Oliver 2018). Others have pointed to social networks such as the 'transition initiative' (Hopkins 2010), eco-village networks (Barani et al. 2018), civil-society movements (Seyfang and Smith 2007) and intentional communities (Grinde et al. 2018; Veciana and Ottmar 2018) as ways of generating the shared understandings that are central to inner and outer transitions, as well as the broader development of social movements. In some cases, these networks build on principles like permaculture to encourage people to 'observe and interact', 'produce no waste' and 'design from patterns to details', not only in agriculture and gardening, but also in sustainable businesses and technologies to reduce CO₂ emissions (Ferguson and Lovell 2014; Lessem 2018).

A related line of inquiry involves education for sustainable development (ESD). This builds on the UNESCO programme, 'ESD for 2030', and involves core values like peace culture, valuing cultural diversity and living global citizenship. One of the core insights from research on ESC is lifelong education continuing outside the classroom, a lifelong learning process that involves sustained actions by all ages and social segments (Hume and Barry 2015) and achieving collaboration (Munger and Riemer 2012). Some authors have pointed to good levels of communication either directly or through the internet as the key to facilitating this learning (Sandfort and Quick 2015). Others have noted that transformative learning – that is, deepening the learning process – is critical because it helps to induce both shared awareness and collective actions (Brundiers et al. 2010; Singleton 2015; Wamsler and Brink 2018).

A final area of work points to the importance of moving toward the knowledge production that underpins awareness-raising (Pelling et al. 2015). The accumulation of applied knowledge is leading increasingly to the co-design of participatory research with local stakeholders who are investigating and transforming their own situations in line with climate action and sustainable development (Wiek et al. 2012; Abson et al. 2017; Fazey et al. 2018).

17.4.1.2 Habits, Values and Awareness

Many of the cases that explore transitions to sustainable development point to ingrained habits, values and awareness levels as the most persistent yet least visible barriers to a transition. For example, in the transport sector, individuals can quickly become accustomed to personal vehicles, making it difficult for them to transition to sustainable, low-carbon modes of public transport. Demand for high-carbon transportation may also be locked-in, and habits reinforced, if low-cost housing (for instance) is not sufficiently served by more sustainable (i.e., mass transit, safe cycling and walking infrastructure) transportation options (Mattioli et al. 2020).

This is made all the more challenging because car-manufacturing ‘incumbents’ utilise information campaigns directed at the public, pursue lobbying and consulting with policymakers, and set technical standards that privilege the status quo and prevent the entry of more sustainable innovations (Smink et al. 2015; Turnheim and Nykvist 2019). Tools such as congestion pricing, however, have been shown to be effective in motivating the switch from single-occupancy vehicle use to public transit, thus improving air quality and reducing traffic delays in dense city centres (Baghestani et al. 2020).

Complicating the problem further is that even well-intentioned top-down programmes initiated by an external actor may in some cases ultimately hinder transformative change (Breukers et al. 2017). For instance, in Delhi, India, attempts to introduce ostensibly more sustainable bus rapid transit (BRT) systems failed in part due to an arguably top-down approach that had limited public support. It may nonetheless be difficult to win public support (Bachus and Vanswijgenhoven 2018), and even grassroots initiatives may themselves be contested and dynamic, making it difficult to generate the collective push to drive a bottom-up transition forward (Hakansson 2018).

However, dominant, top-down approaches and local, grassroots ‘alternative’ approaches and values do overlap and interact. For example, in Manchester, UK, dominant and alternative discourses interact with each other to create sustainable transformations through re-scaling (decentralising) energy generation, creating local engagement with sustainability, supporting green infrastructure to reduce costs, reclaiming local land, transforming industrial infrastructure and creating examples of sustainable living (Hodson et al. 2017).

Embedding local values in higher-level policy frameworks is also significant for forest communities in Nepal and Uganda. Even so, policy intermediaries are not confident that these values will be advanced due largely to an emphasis on carbon accounting and the distribution of benefits (Reckien et al. 2018). In this case, however, norm entrepreneurs were able to promote the importance of local values through the formation of grassroots associations, media campaigns and international support networks (Reckien et al. 2018).

17.4.2 Technological and Social Innovation

Individuals and organisations, like institutional entrepreneurs, can function to build transformative capacity through collective action (Brodnik and Brown 2018). The transition from a traditional water-management system to the Water Sensitive Urban Design (WSUD) model in Melbourne offers an illustration of how whole systems can be changed in an urban system.

Private-sector entrepreneurs also play an important role in fostering and accelerating transitions to sustainable development (Burch et al. 2016; Ehnert et al. 2018a; Dale et al. 2017). Sustainable entrepreneurs (SEs), for instance, are described as those who participate in the development of an innovation while simultaneously being rooted in the incumbent energy-intensive system. SE actors who have developed longer-term relationships, both formal and informal, with the public authorities can have considerable influence on developing novel renewable-energy technologies (Gasbarro et al. 2017). Institutions and policies that nurture the activities of sustainable entrepreneurs, in particular small- and medium-sized enterprises (Burch et al. 2016), can facilitate and strengthen transitions toward more sustainable development pathways, as can more fundamental adjustments to underlying business models, rather than relying only on incremental adjustments in the efficiency with which resources are used (Burch and Di Bella 2021).

The creation and growth of sustainable energy and clean-tech clusters enable economic development and transformation on regional scales. Such clusters can put pressure on incumbent technologies and rules to accelerate energy transitions. Successful clusters are nurtured by multi-institutional and multi-stakeholder actors building institutional support networks, facilitating collaboration between sectors and actors, and promoting learning and social change. Notably, regional economic clusters generate a buzz, which can have a strong influence on public acceptance, support and enthusiasm for socio-technical transitions (McCauley and Stephens 2012).

In Norway, many incumbent energy firms have already expanded their operations into the alternative-energy sector as both producers and suppliers (who often follow the lead of producers). Producers are responding to perceptions of larger-scale changes in the energy landscape (e.g., the green shift), along with uncertainties in their own sectors, and innovation can spill across actors in multiple sectors (Koasidis et al. 2020). While these firms are expanding out of self-interest, the expansion provides more legitimacy to new forms of technology and enables transfers of knowledge and resources to be introduced within this developing niche (Steen and Weaver 2017). Many large, well-established firms are pursuing sustainability agendas and opting for transparency with regard to their greenhouse gas emissions (Kolk et al. 2008; Guenther et al. 2016), supply-chain management (Formentini and Taticchi 2016) and sustainable technology or service development (Dangelico et al. 2016).

Experiments with the transition open up pathways that can lead to energy transitions on broader scales. Experiments can build capacity by developing networks and building bridges between diverse actors, leveraging capital from government funds, de-risking private- and public-sector investment, and acting as hubs for public education and engagement (Rosenbloom et al. 2018).

Material barriers and spatial dynamics (Coenen et al. 2012; Hansen and Coenen 2015) are other critical obstacles to innovation: often, infrastructure and built environments change more slowly than policies and institutions due to the inherently long lifespans of fixed assets (Turnheim and Nykvist 2019). The example of transport infrastructure in Ontario, Canada, illustrates the need to integrate climate change into these infrastructural decisions in the very short term to combat the risk of being left with unsustainable planning features long into the future, especially combustion engines, significant road networks and suburbanisation (Birch 2016).

17.4.3 Financial Systems and Economic Instruments

Market-oriented policies, such as carbon taxes and green finance, can promote low-carbon technology and encourage both private and public investment in enabling transitions. Policies that are currently being tested include loan guarantees for renewable-energy investments in Mali, policy insurance to reduce credit defaults within the feed-in tariff regime in Germany, or pledged funding to fully finance or partner private firms in order to advance renewable-energy projects (Roy et al. 2018a). However, there may be some limitations in using carbon pricing alone (rather than in combination with flexible regulations and incentives) where market failures hinder low-carbon investments (Campiglio 2016; World Bank 2019) and high political costs are incurred (Van Der Ploeg 2011).

Many forms of transformational change to energy systems are not possible when financial systems still privilege investing in unsustainable, carbon-intensive sectors. One of the root causes of the failure of traditional financial systems is the undervaluation of natural capital and unsettled property-right issues that are associated with it. The exclusion of proper rents for scarcities or for global and local externalities, including climate change, can undermine larger-scale changes to energy systems (Clark et al. 2018). But even smaller-scale low-carbon energy and infrastructure projects can fail to get off the ground if uncertainty and investment risk discourage project planning and bank-lending programmes (Bolton et al. 2016). The EU's previous actions regarding the 'shareholder maximisation norm' and non-binding measures have created path dependencies, limiting its flexibility in creating sustainable financial legislation. However, the Sustainable Finance Initiative and the Single Market may prove to be 'policy hotspots' in encouraging sustainable finance (Ahlström 2019). Taking advantage of these hotspots may be crucial in overcoming path dependencies and setting new ones in motion.

One possible positive turn in this regard is the acceleration in investing in the environment (impact and ESG) globally: for instance, there is evidence that some institutional investors are divesting from coal, potentially auguring well for the future (Richardson 2017).

The encouragement of governance and policy reforms that could facilitate similar expansions of investment in sustainable firms and sectors (Clark et al. 2018; Owen et al. 2018) could contribute to the dynamic feedback that gives a transition lift and injects momentum into it. Also, the degrowth movement, with its focus on sustainability over profitability, has the potential to speed up transformations using alternative practices such as fostering the exchange of non-monetary goods and services if large numbers of stakeholders want to invest in these areas (Chiengkul 2017).

17.4.4 Institutional Capacities and Multi-level Governance

Capable institutions and multi-level governance often support the inter-agency coordination and stakeholder coalitions that drive sustainable transitions. Such institutions and governance arrangements are frequently required to formulate and implement the multi-sectoral policies that spur the adoption and scaling of innovative solutions to climate change and other sustainable development challenges. For example, such institutional and governance conditions have helped support the industrial policies that will be needed to spread renewables through the creation of domestic supply chains (Zenghelis 2020) or to pilot CDR methods (Quarton and Samsatli 2020).

However, government agencies with climate and other remits do not always work well together: the absence of coordination and consensus-building mechanisms can further deepen inter-agency conflicts that stall a transition. These challenges appear not only within but also between levels of decision-making. Studies of developing megacities, for instance, have found the lack of mechanisms promoting vertical cross-level integration to be a sizeable constraint on decarbonisation (Canitez 2019). Differences in perspectives across non-state actors can similarly frustrate transitions in areas such as green buildings (Song et al. 2020).

Here coordination complicates matters: coalition-building may require mutually reinforcing changes to institutions and policies. For example, decentralised renewable energy has made progress in Argentina, but consumer electricity subsidies give agencies and firms supporting conventional energy an advantage over those promoting renewable energy. Similarly, the lack of concrete guidance in green finance policies can deprive government agencies and other stakeholders of the information needed to balance ecological and financial goals (Wang and Zhi 2016). Many of these challenges can be particularly formidable in developing countries, where agencies lack sufficient financial and other capacities. A lack of government funds to cover ongoing maintenance costs along with resource shortages in rural locations can pose constraints on sustainable energy (Schaube et al. 2018).

Building inter-agency or multiple stakeholders is frequently challenging because of the mutually reinforcing interactions between institutions and ideas. The imperceptible embedding of long-standing development paradigms (such as 'grow now, clean up later') in agency rules and standard operating procedures can make

changes to governance arrangements challenging. This is partly because these rules and procedures can also shape the interests of key decision-makers (e.g., the head of an environmental agency). For some, this suggests a need to look not just at changing prevailing ideas and interests, but also at broader institutional and governance arrangements (Kern 2011).

However, institutional and governance reforms can be more than a technical exercise. Political, economic and other power relations can lock-in dominant institutional and economic structures, making the integration of climate and sustainable development agendas exceedingly difficult. For example, though there have been recent reforms, the initial lack of early progress in Australia's energy transition is partly attributable to institutions of political economy being oriented to providing steady supplies of affordable fossil fuels (Warren et al. 2016).

This suggests that it is important to look closely at the pre-existing political economic system as well as the institutional context and capacities in assessing the prospects for transitions to sustainability. Furthermore, this is how existing institutions interact with ideas that often strengthen lock-ins. To illustrate, studies have shown that the status-quo orientations of leaders (including decision-makers' disciplinary backgrounds, world views and perceptions of risk) (Willis 2018), as well as the organisational culture and management paradigms within which they operate, affect the speed and ambitions of climate policies (Rickards et al. 2014).

Some studies have focused on factors that can break institutional and ideational lock-ins (Arranz 2017), while others have found that intentional higher-level (or, in the language of socio-technical transitions, 'landscape') pressures can be the destabilising force needed to move transitions forward (Falcone and Sica 2015). Often the state or national government (as the sovereign that determines how resources are used and allocated) can play a key role in destabilising incumbent energy regimes, a role that is significantly strengthened by public support (Arranz 2017; Avelino et al. 2016). However, this role is not limited to government insiders. In some contexts, regime outsiders have also played a pivotal role in destabilising regimes by combining persuasive narratives that gain market influence (Arranz 2017). Carbon-intensive luxury goods and services for wealthy consumers, for instance, especially if applied at the 'acceleration' phase of a transition, can help transform long-term social practices and behaviour and dissolve the 'structural imperative for growth' (Wiedmann et al. 2020). In a similar fashion, environmental taxes can remove 'locked-in' technology and place pressure on dominant regimes to become more sustainable (Bachus and Vanswijgenhoven 2018).

In many contexts, it is not multiple institutional and policy variables that come together to break unsustainable inertias. In South Korea, where the state was an initiator and enabler of change, the clean-energy transition took much longer than anticipated due to private-sector resistance. However, when policymakers focused on incorporating adaptive learning and flexibility into their decision-making, public- and private-sector interests gradually converged and joined with top-down policymaking to drive the transition forward

(Lee et al. 2019). Thus, a political strategy can help align the interests and institutions needed to break lock-ins.

This becomes clear in studies that show that political coalitions can affect the speed of transitions (Hess 2014). These same studies show that incumbent industry coalitions are now competing with 'green' coalitions in terms of campaign spending over environmentally friendly ballot proposals (Hess 2014). Another way of shifting political-economic incentives is by offering a realistic exit strategy for incumbents, like interventions that provide long-term incentives for renewable-energy firms (de Gooyert et al. 2016; Hamman 2019).

Overall, the previous subsection suggests that complementary policies and institutions that simultaneously integrate across multiple sectors and scales and also alter political economic structures that lock in a carbon-intensive energy system are more likely to move a sustainable transition forward (Burch 2010). Yet, despite a trend in climate governance towards greater integration and inclusivity and certain other novel governance approaches, traditional approaches to governance and a tendency to incrementalism remain dominant (Holscher et al. 2019). Building the governance arrangements and capacities that prioritise climate change across all sectors and scales while destabilising entrenched interests and putting pressure on existing norms, rules and practices is still needed in many contexts (Holscher et al. 2019).

At least three themes require further research in the scholarship on the governance of transitions: (i) the role of coalitions in supporting and hindering acceleration; (ii) the role of feedback, through which policies may shape actor preferences, which in turn create stronger policies; and (iii) the role of broader contexts (political economies, institutions, cultural norms, and technical systems) in creating conditions for acceleration (Roberts et al. 2018). Importantly, these themes may serve as both barriers to and opportunities for transitions (ibid.).

17.4.5 Equity in a Just Transition

Energy justice, although increasingly being emphasised (Pellegrini-Masini et al. 2020), has been under-represented in the literature on sustainability and in debates on energy transitions, and it remains a contested term with multiple meanings (Green and Gambhir 2020). Energy justice includes affordability, sustainability, equality (accessibility for current and future households) and respect (ensuring that innovations do not impose further burdens on particular groups) (Fuso Nerini et al. 2019). Furthermore, it suggests that a just transition is a shared responsibility among countries that are making more rapid progress towards net-negative emissions and those economies that are focused on pressing development priorities related to improved health, well-being and prosperity (van den Berg et al. 2020).

Looking at climate change from a justice perspective means placing the emphasis on (i) the protection of vulnerable populations from the impacts of climate change; (ii) mitigating the effects of the transformations themselves, including easing the transition for those whose livelihoods currently rely on fossil fuel-based sectors;

and (iii) envisaging an equitable decarbonised world. Neglecting issues of justice risks a backlash against climate action generally, particularly from those who stand to lose from such actions (Patterson et al. 2018), and it will also have implications for the pace, scale and quality of the transition. Explicit interventions to promote sustainability transitions that integrate local spaces into the whole development process are necessary but not sufficient in creating a just transition (Breukers et al. 2017; Ehnert et al. 2018b).

Renewable energy transitions in rural, impoverished locations can simultaneously reinforce and disrupt local power structures and inequalities. Policy interventions to help the most impoverished individuals in a community gain access to the new energy infrastructure are critical in ensuring that existing inequalities are not reinforced. Individuals who are empowered by energy development projects can influence the onward extension of sustainable energy to other communities (Ahlborg 2017). In Denmark in the 1970s, for example, grassroots windmill cooperatives opened a pathway to the creation of one of the world's largest wind-energy markets. The unique dynamics of grassroots-led changes mean that new technologies and low-carbon initiatives develop strong foundations by being designed, tested and improved in the early stages with reference to the socio-political contexts in which they will grow later (Ornetzeder and Rohrer 2013).

Intersectional theory can shine a light on the hidden costs of resource extraction, as well as renewable-energy development (see, for instance, Chatalova and Balmann 2017), which go beyond environmental or health risks to include the socio-cultural impacts on both communities adjacent to these sites and those who work in them (Daum 2018). Indeed, development decisions often do not properly integrate the burdens and risks placed on marginalised groups, such as indigenous peoples, while risk assessments tend to reinforce existing power imbalances by failing to differentiate between how benefits and risks might impact on certain groups (Healy et al. 2019; Kojola 2019). In some cases, such as the deployment of small-scale solar power in Tanzania by a non-profit organisation, an explicit gender lens on the impacts of energy poverty revealed the significant socio-economic benefits of improving access to renewable energy (Gray et al. 2019).

17.4.6 Holistic Planning and the Nexus Approach

Poor sectoral coordination and institutional fragmentation have triggered a wide range of unsustainable uses of resources and threatened the long-term sustainability of food, water and energy security (Rasul 2016). Greater policy coherence among the three sectors is critical to moving to a sustainable and efficient use of resources (United Nations 2019), given that political ambition, values, the energy mix, infrastructure and innovation capacities collectively shape transition outcomes (Neofytou et al. 2020). Capacity- and coalition-building, particularly among sub-national and non-state actors (e.g., non-governmental organisations) is a particularly important enabler of greater coherence (Bernstein and Hoffmann 2018). The nexus approach, a systems-based methodology that focuses attention on the many ways in which natural resources are deeply interwoven and mutually interdependent, can

strengthen coordination and help to avoid maladaptive pathways (Cremades et al. 2016).

A major shift is required in the decision-making process in the direction of taking a holistic view, developing institutional mechanisms to coordinate the actions of diverse actors and strengthening complementarities and synergies (Nikas et al. 2020; Rasul 2016). Currently, nexus approaches have moved from purely conceptual arguments to application and implementation. (Liu et al. 2018) suggest the need for a systematic procedure and provide perspectives on future directions. These include expanding nexus frameworks that take into account interaction linkages with the SDGs, incorporating overlooked drivers and regions, diversifying nexus toolboxes and making these strategies central to policymaking and governance in integrating and implementing the SDGs.

In respect of processes, (Seyfang and Haxeltine 2012) found a lack of realistic and achievable expectations among both members (internally) and the wider public (externally), which hampers the acceleration of transitions. This movement could concentrate strategically on developing and promoting short-term steps towards shared long-term visions, including clearly identifiable goals and end-points. Sustainability science must link research on problem structures with a solutions-oriented approach that seeks to understand, conceptualise and foster experiments in how socio-technical innovations for sustainability develop, are diffused and are scaled up (Miller et al. 2014).

Various strategies and processes have been explored that might facilitate the translation of barriers into enablers, thus accelerating transitions to sustainable development. Common themes include frequent monitoring and system evaluation to reveal the barriers in the first place, the collaborative co-creation and envisioning of pathways toward sustainable development, ambitious goal-setting, the strategic tackling of sources of path dependence or inertia, iterative evaluations of progress and risk management, adaptive management and building in opportunities for agile course-correction at multiple levels of governance (Burch et al. 2014; Halbe et al. 2015). Given the political infeasibility of stable, long-term climate policies, the better choice may be to embrace uncertainty in specific policies but entrench the low-carbon transition as the overarching goal. Framing climate policy too narrowly, rather than taking a more holistic, sustainable development-oriented approach, may tie success to single policies, rather than allowing for system-wide change.

Decarbonisation may be encouraged by embedding the transition in a broader socio-economic agenda, focusing on constructing social legitimacy to justify the transformation, encouraging municipalities with a material interest in the transition and reforming institutions to support the long-term transition goals (Rosenbloom et al. 2019). In jurisdictions where climate and energy policy have been integrated and harmonised, such as the UK, progress has been made in transitioning to sustainable energy (Warren et al. 2016).

Developing countries that are rich in fossil fuels now have an opportunity to reset their development trajectories by focusing on those opportunities that will offer resilient development in land-use

change, low-carbon energy generation and not least more efficient resource-planning (UNDRR 2019). Resource-rich developing countries can choose an alternative pathway by deciding to monetise carbon capital and diversifying away from the high-carbon aspects of risk. Countries rich in hydrocarbons can diversify their energy mix and maximise their renewable-energy potential. For instance, Namibia, a net importer of electricity, is seeking to reduce its current dependence on hydrocarbons by promoting solar energy. The government has issued permits allowing independent power producers (IPPs) to sell directly to consumers, thus ending the monopoly hitherto enjoyed by the state utility company NamPower (Kruger et al. 2019).

Cities are important spaces where the momentum to achieve low-carbon transitions can be built (Burch 2010; Holscher et al. 2019; Shaw et al. 2014), especially where centralised energy structures and national governance and politics are posing deep-rooted challenges to change (Dowling et al. 2018; Meadowcroft 2011). Cities can enter networks and partnerships with other cities and multi-level actors, spaces that are important for capacity-building and accelerating change (Dale et al. 2020; Heikkinen et al. 2019; Westman et al. 2021).

Addressing the uncertainties and complexities associated with locally, regionally and nationally sustainable development pathways requires creative methods and participatory processes. These may include powerful visualisations that make the implications of climate change (and decarbonisation) clear locally (Shaw et al. 2014; Sheppard et al. 2011), other visual aids or 'progress wheels' that effectively communicate the relevant contexts (Glaas et al. 2019), storytelling and mapping, and both analogue and digital games (Mangnus et al. 2019).

17.5 Conclusions

This chapter has been concerned to assess the opportunities and challenges for acceleration *in the context of sustainable development*. As such, many of the claims reviewed involve not only increasing the speed of the transition but also ensuring that it is just, equitable and delivers a wider range of environmental and social benefits. A sustainability transition requires removing the underlying drivers of vulnerability and high emissions (quality and depth) while aligning the interests of different communities, regions, sectors, stakeholders and cultures (scale and breadth).

Interest in a sustainability transition has grown steadily over the history of the IPCC and of climate and related policy processes. That interest hit a high point in 2015 with the Paris Agreement and the UN 2030 Agenda for Sustainable Development and its 17 SDGs. It has continued to remain high as countries have issued NDCs on climate change, VNRs on the SDGs and, in some instances, integrated climate and SDG plans (or similarly themed integrated actions, e.g., circular economy plans). Interest has also gained momentum as local governments, businesses and other stakeholders have followed suit with climate change- or SDG-related plans.

Implementing many of the recent pledges, however, has proved challenging. Part of the challenge is a need to address everything from public policies and prevailing technologies to individual lifestyles and social norms, to governance arrangements and institutions with

associated political economy implications. These factors can lock-in development pathways and prevent transitions from gathering the momentum needed for large-scale transformations of socio-economic systems. Another consideration is that transition pathways are likely to vary across and within countries due to different development levels, starting points, differential vulnerabilities, capacities, agencies, geographies, power dynamics, political economies, ecosystems and other contextual factors.

Even with this diversity, prominent lines of economic, institutional, psychological and systems thinking have reflected on interventions that can enable transitions. Because these disciplines often focus on different levels of analysis and draw upon diverse analytical methods and empirical evidence, the recommended interventions also tend to vary. For instance, economic arguments often point to the need for targeted regulation or investments, institutional claims centre on multi-level governance reforms, and psychology encourages participation to change mindsets and social norms. Systems-level perspectives offer a useful frame for bringing together these views, but may not capture the richness and details of them treated separately. Greater inter- and transdisciplinary research is needed to integrate the more focused interventions and show how they work together in a system. Such research will be particularly important for working on the concern running through these studies: strengthening synergies between climate and the broader sustainable development agenda.

National and sub-national, sectoral and cross-sectoral, short- and long-term transition studies have assessed the links between sustainable development and mitigation policies and synergies and the trade-offs between the different policy domains. Some general conclusions can be drawn on synergies and trade-offs, despite the actual impacts of policy implementation depending on scale, context and the development starting point.

From a cross-sectoral perspective, it can be concluded that the AFOLU sector offers many low-cost mitigation options with synergetic SDG impacts, which, however, can also create trade-offs between land use for food, energy, forest and biodiversity. Some options can help to mitigate such trade-offs, like agricultural practices, forest conservation and soil carbon sequestration. Lifestyle changes, including dietary changes and reduced food waste, could jointly support the SDGs and mitigation. Industry also offers several mitigation options with SDG synergies, for example, related to energy efficiency and the circular economy. Some of the renewable-energy options in industry could indicate some trade-offs in relation to land use, with implications for food- and water security and costs. Cities provide a promising basis for implementing mitigation with SDG synergies, particularly if urban planning, transportation, infrastructure and settlements are coordinated jointly. Similarly, studies of the building sector have identified many synergies between the SDGs and mitigation, but there are issues related to the costs of new technologies. Also, in relation to households and buildings, important equity issues emerge due to the ability of low-income groups to afford the introduction of new technologies. Altogether these cross-sectoral conclusions create a need for policies to address both synergies and trade-offs, as well as for coordination between different sectoral domains. Context-specific assessments of synergies and trade-offs are here important, as is sharing the benefits and costs associated with mitigation policies.

Several opportunities for creating SDG synergies and avoiding trade-offs have also been identified in relation to integrated adaptation and mitigation policies. The AFOLU sector has a large potential for integrating adaptation and mitigation policies related to agriculture, bioenergy crops, forestry and water use. As was concluded for mitigation options, integrated adaptation and mitigation policies also entail the risks of creating trade-offs in relation to food, water, energy access and biodiversity. There are several potentially strong links between climate change adaptation in industry and climate change adaptation more generally. Various supply chains can be affected by climate change, and mitigation options related to energy and water supply can be disrupted by climate events, implying that great benefits may come from integrating adaptation in industrial planning efforts. Adaptation options in industry can imply increasing the demand for packaging materials such as plastics and for access to refrigeration, which are also major sources of GHG emissions, which then would require further mitigation options. Mitigation and the co-benefits of adaptation in urban areas in relation to air quality, health, green jobs and equality issues can in most cases be synergetic and can also support the SDGs. One exception are compact cities, with their trade-offs between mitigation and adaptation because decreasing urban sprawl can increase the risks of flooding and heat stress. Detailed mapping of mitigation and adaptation in urban areas shows that there are many, very close interactions between the two policy domains and that coordinated governance across sectors is therefore called for.

Meeting the ambitions of the Paris Agreement will require phasing out fossil fuels from energy systems, which is technically possible and is estimated to be relatively low in cost. However, studies also show that replacing fossil fuels with renewables can have major synergies and trade-offs with a broader agenda of sustainable development if a balance is established in relation to land use, food security and job creation (McCollum et al. 2018). Furthermore, the transition to low-emission pathways will require policy efforts that also address the emissions locked-in to existing infrastructure, like power plants, factories, cargo ships and other infrastructure already in use: for example, today coal-fired power plants account for 30% of all energy-related emissions. Thus, even though the transition away from fossil fuels is desirable and technically feasible, it is still largely constrained by existing fossil fuel-based infrastructure and the existence of stranded investments. The 'committed' emissions from existing fossil fuel infrastructure may consume all the remaining carbon budget in the 1.5°C scenario or two thirds of the carbon budget in the 2°C scenario.

Stranded hydrocarbon assets, including hydrocarbon resources and the infrastructure from which they are produced, and investments made in exploration and production activities, are likely to become unusable, lose value or may end up as liabilities before the end of the anticipated economic lifetime. This phenomenon is rapidly becoming a global reality as social norms change and the pressure to reduce emissions mounts. Energy and other forms of structural inequities are likely to make the transition planning more challenging, especially given stranded assets.

Countries dependent on fossil fuel income will need to forego these revenues to keep well within the Paris Agreement requirements and align with the rapidly growing divestment movement. Climate injustice, energy poverty and COVID-19 have reduced the space

and manoeuvrability for developing countries to innovate and use surplus funds to procure new and clean technologies. A rising debt burden already hamstrings many. Decisions on how to spend the remaining carbon budget and who has the right to decide on what to do with existing fossil fuels reflect the complexity of the transition and its non-linear character. Given the asymmetrical dimension of energy production, distribution and use, it is likely that stranded assets will have implications for oil-producing countries, especially for early producers who perceive that new-found oil and gas will open doors to new forms of prosperity.

While the transitional drivers are not in place in some developing countries, that is, technology, infrastructure, knowledge, and finance, among others, investing in new forms of renewable energy for the land, energy, or water sectors will see the emergence of a more diversified economy and one less vulnerable to carbon and other exogenous risks. The transition away from fossil fuels will come with hard choices. Still, these choices can enable a sustainable development world and reduce the many asymmetries and injustices inherent in the current system, not least the gaping energy disparities that divide the developed and the developing world.

Equality and justice are central dimensions of transitions in the context of sustainable development. Viewing climate change through the lens of justice requires a focus on the protection of vulnerable populations from the impacts of climate change, addressing the unequal distribution of the costs and consequences of the transitions themselves, including for those whose livelihoods are rooted in fossil fuel-based sectors, and developing more creative and participatory processes for envisioning an equitable decarbonised world. Neglecting issues of justice will have implications for the pace, scale and quality of the transition.

Ultimately, the evidence demonstrates that there is rarely any one single factor promoting or preventing transitions. A constellation of elements come into play, including technological innovations, shifts in markets, social and behavioural dynamics, and governance arrangements. Indeed, transitions require an examination of the role of values, attitudes, beliefs and the structures that shape behaviour, as well as the dynamics of social movements and education at multiple levels. Likewise, technological and social innovation both play an important role in enabling transitions, highlighting the importance of multi-institutional and multi-stakeholder actors building institutional support networks, facilitating collaboration between sectors and actors, and promoting learning and social change. Financial tools and economic instruments are crucial enablers, since many forms of transformational change to energy systems are not possible when financial systems still privilege investing in unsustainable, carbon-intensive sectors. These instruments are deployed within the context of the multi-level governance of climate change, which suggests the importance of complementary policies and institutions that simultaneously integrate across multiple sectors and scales to address the multiple sources of lock-in that are shaping the current carbon-intensive energy system. Systems-oriented approaches, which holistically address the intersections among climate, water and energy (for instance), have significant potential to reveal and help avoid trade-offs, foster experimentation, and deliver a range of co-benefits on the path towards sustainable development.

Frequently Asked Questions (FAQs)

FAQ 17.1 | Will decarbonisation efforts slow or accelerate sustainable development transitions?

Sustainable development offers a comprehensive pathway to achieving ambitious climate change mitigation goals. Sustainable development requires the pursuit of synergies and the avoidance of trade-offs between the economic, social and environmental dimensions of development. It can thus provide pathways that accelerate progress towards ambitious climate change mitigation goals. Factoring in equality and distributional effects will be particularly important in the pursuit of sustainable policies and partnerships, and in accelerating the transition to sustainable development. Using climate change as a key conduit can only work if synergies across sectors are exploited and if policy implementation is supported by national and international partnerships.

The speed, quality, depth and scale of the transition will depend on the developmental starting point, that is, on explicit goals as well as the enabling environment consisting of individual behaviour, mindsets, beliefs and actions, social cohesion, governance, policies, institutions, social and technological innovations, and so on. The integration of both climate change mitigation and adaptation policies in sustainable development is also essential in the establishment of fair and robust transformation pathways.

FAQ 17.2 | What role do considerations of justice and inclusivity play in the transition towards sustainable development?

Negative economic and social impacts in some regions could emerge as a consequence of ambitious climate change mitigation policies if these are not aligned with key sustainable development aspirations such as those represented by the Sustainable Development Goals (SDGs) on 'no poverty, energy-, water- and food access', and so on, which could in turn slow down the transition process. Nonetheless, many climate change mitigation policies could generate incomes, new jobs and other benefits. Capturing these benefits could require specific policies and investments to be targeted directly towards including all parts of society in the new activities and industries created by the climate change mitigation policies, and that activities that are reduced in the context of transitions to a low-carbon future, including industries and geographical areas, are seeing new opportunities. Poor understanding of how governance at multiple levels can meet these challenges to the transition may fail to make significant progress in relation to national policies and a global climate agreement. It may therefore either support or weaken the climate architecture, thus constituting a limiting factor.

FAQ 17.3 | How critical are the roles of institutions in accelerating the transition and what can governance enable?

Institutions are critical in accelerating the transition towards sustainable development: they can help to shape climate change response strategies in terms of both adaptation and mitigation. Local institutions are the custodians of critical adaptation services, ranging from the mobilisation of resources, skills development and capacity-building to the dissemination of critical strategies. Transitions towards sustainable development are mediated by actors within particular institutions, the governance mechanisms they use as implementing tools and the political coalitions they form to enable action. Patterns of production and consumption have implications for a low-carbon development, and many of these patterns can act as barriers or opportunities towards sustainable development. Trade policies, international economic issues and international financial flows can positively support the speed and scale of the transition; alternatively, they can have negative impacts on policies that may inhibit the process. Nonetheless, contextual factors are a fundamental part of the change process, and institutions and their governance systems provide pathways that can influence contextual realities on the ground. For instance, politically vested interests may lead powerful lobby groups or coalition networks to influence the direction of the transition, or they could put pressure on a given political elite through the imposition of regulatory standards, taxation, incentives and policies that may speed or delay the transition process. Civil-society institutions, such as NGOs or research centres, can act as effective governance 'watchdogs' in the transition process, particularly when they exercise a challenge function and question government actions in respect of transitions related to sustainable development.

Accelerating the Transition in the Context of Sustainable Development Supplementary Material

Coordinating Lead Authors:

Fatima Denton (the Gambia), Kirsten Halsnæs (Denmark)

Lead Authors:

Keigo Akimoto (Japan), Sarah Burch (Canada), Cristobal Diaz Morejon (Cuba), Fernando Farias (Chile), Joni Jupesta (Indonesia/Japan), Ali Shareef (Maldives), Petra Schweizer-Ries (Germany), Fei Teng (China), Eric Zusman (the United States of America)

Contributing Authors:

Fátima Antonethe Castaneda Mena (Guatemala), Morten Andreas Dahl Larsen (Denmark), Shreya Some (India)

Review Editors:

Diriba Korecha Dadi (Ethiopia), Hermann Held (Germany)

Chapter Scientist:

Fátima Antonethe Castaneda Mena (Guatemala)

Table 17.SM.1 | Chapter 6.

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Energy systems	Wind energy	+ Wind can provide low-cost electricity to several communities (<i>high confidence</i>)	± Land use for wind energy needs to be coordinated based on local circumstances, otherwise can have negative implications on food security (<i>medium confidence</i>)	+ Minimal air pollution, also integration with health sector frequently discussed (<i>high confidence</i>)			+ Low consumption of water (<i>high confidence</i>)	+ Low-cost and low-carbon electricity in several regions (<i>high confidence</i>)	+ Large job creation per unit investment (<i>medium confidence</i>)	+ Integration with offshore and other infrastructure (<i>medium confidence</i>)		+ Could help through net metering (<i>medium confidence</i>)	± Cater to sustainable production, however has significant material consumption and disposal needs (<i>medium confidence</i>)	+ Low-carbon emissions (<i>high confidence</i>)	± Offshore wind could pose risk to marine life if not appropriately managed (<i>high confidence</i>)	± Land use for wind energy needs to be coordinated, otherwise can have negative implications on biodiversity (<i>medium confidence</i>)			Sections 6.4.2.2 and Section 6.7.7	Need large storage infrastructure associated with their system integration. Will likely require significantly more critical minerals Key context would include availability of land that does not compromise biodiversity
	Solar energy	+ Solar PV can provide low-cost electricity to several communities (<i>high confidence</i>)	± Land use for solar energy needs to be coordinated based on local circumstances, otherwise can have negative implications on food security (<i>medium confidence</i>)	+ Minimal air pollution, also integration with health sector frequently discussed (<i>high confidence</i>)			± Low consumption of water for PV but higher for CSP (Concentrating Solar Power) (<i>high confidence</i>)	+ Low-cost and low-carbon electricity in several regions (<i>high confidence</i>)	+ Large job creation per unit investment (<i>medium confidence</i>)	+ Solar heat may be used in industrial heating (<i>medium confidence</i>)		+ Could help through net metering (<i>medium confidence</i>)	± Cater to sustainable production, however has significant material consumption and disposal needs (<i>medium confidence</i>)	+ Low-carbon emissions (<i>high confidence</i>)		± Land use for solar energy needs to be coordinated, otherwise can have negative implications on biodiversity (<i>medium confidence</i>)			Sections 6.4.2.1 and Section 6.7.7	Key context would include availability of land that does not compromise biodiversity. Moreover, coordination with materials cycles is needed Need large storage infrastructure associated with their system integration. Will likely require significantly more critical minerals
	Bioenergy	± Bioenergy may be useful to provide rural energy. But large-scale bioenergy projects with CCS may be expensive (<i>medium confidence</i>)	± Farm employment and incomes could increase, which is a key component of SDG 2 (2.3 to be specific). The reason for the tradeoff is competition between food and bioenergy crops (<i>medium confidence</i>)	± Depending on the scale and infrastructural efficacy, bioenergy may result in good or poor air quality (<i>medium confidence</i>)			± Some bioenergy feedstocks may cause competition for water (<i>high confidence</i>)	± Significant potential to deliver low-carbon or carbon-negative energy. High dependence of 2.2 billion people on traditional and non-sustainable biomass, with negative impact on health and deforestation (<i>high confidence</i>)	+ Potential to provide employment, including to workers who may be transitioning from fossil sectors (<i>high confidence</i>)	+ Considerable opportunities for integration with other industries such as wastewater treatment (<i>high confidence</i>)		+ Could lead to low-carbon transport fuels (<i>high confidence</i>)	+ Use of waste biomass could be useful (<i>high confidence</i>)	+ Low-carbon emissions (<i>high confidence</i>)	± Treatment of nutrient-rich wastewater (which produces biogas as a co-benefit) is highly relevant for SDG 14.1 – Reduce marine pollution. At the same time, effluents from biofuel production can also cause negative impacts on marine ecosystems when effluent treatment is not meeting high standards (<i>high confidence</i>)	± Land use needs to be coordinated, otherwise can have negative implications on biodiversity and food production (<i>high confidence</i>)			Sections 6.4.2.6 and 12.5, Box 6.1	The regional context in terms of the types of biomass/land being utilised is critical Has potential for development of low-carbon organic materials, chemicals and plastics that can be produced
	Hydropower		± Could lead to fisheries damage if not properly managed (<i>medium confidence</i>)	+ Minimal air pollution (<i>high confidence</i>)			+ Coordination with water infrastructure (<i>medium confidence</i>)	+ Low-cost and low-carbon electricity in several regions (<i>high confidence</i>)						+ Low-carbon emissions (<i>high confidence</i>)	± Could lead to fisheries damage if not properly managed (<i>medium confidence</i>)	± Land use needs to be coordinated, otherwise can have negative implications on biodiversity (<i>medium confidence</i>)			Section 6.4.2	Key context would include availability of land that does not compromise biodiversity
	Geothermal energy	+ Potential to provide energy in several energy-scarce regions (<i>low confidence</i>)		± Low air pollution but some water pollution risks (<i>medium confidence</i>)			± Water flowback, water pollution and other issues (<i>medium confidence</i>)	+ Low-cost and low-carbon electricity and heat in several regions (<i>high confidence</i>)		+ Heat may be used in industrial heating (<i>medium confidence</i>)		+ Potential for air conditioning and heating (<i>medium confidence</i>)		+ Low-carbon emissions (<i>high confidence</i>)					Section 6.4.2.8	Would depend on water management infrastructure
	Nuclear power			± Reduced air pollution if displacing fossil. Much Literature on both the health benefits as well as risks arising from such power plants (<i>high confidence</i>)			– Significant water consumption (<i>high confidence</i>)	± Increased use of nuclear power can provide stable baseload power supply and reduce price volatility but has nuclear waste management needs (<i>medium confidence</i>)	+ Local employment and reduced price volatility (<i>medium confidence</i>)	± Could provide low-carbon heat. It differs across countries, whether a country already has a nuclear power or whether it is a newcomer country. In the latter case, a wide range of infrastructure issues need to be addressed, including facilities and equipment, as well as human and financial resources, and the legal and regulatory framework (<i>medium confidence</i>)			± Cater to sustainable production, low resource consumption, but has significant waste management needs (<i>medium confidence</i>)	+ Low-carbon emissions (<i>high confidence</i>)	± Low impacts to ecosystems (acidification, eutrophication, ecotoxicity, ozone depletion). Long-term solutions for high-level radioactive waste are under development (<i>medium confidence</i>)	± Low impacts to biodiversity but high impact in case of an accident (<i>medium confidence</i>)			Section 6.4.2.4, Figure 6.18	Depends on the type of power plants being displaced Nuclear requires significantly less minerals than other low-carbon technologies
	Carbon capture and storage (CCS)			+ CCS infrastructure generally requires reduction of air pollutants for optimal operation (<i>high confidence</i>)			– Water use generally increases significantly; significant water treatment needs may also arise for brines (<i>high confidence</i>)		+ Potential to spur technological innovation; also could reduce inequity risks for fossil workers (<i>high confidence</i>)	+ Could help decarbonise some hard-to-decarbonise sectors (<i>high confidence</i>)			± Use of resources and chemicals could increase unless appropriately managed (<i>medium confidence</i>)	+ Low-carbon emissions (<i>high confidence</i>)					Sections 6.4.2.5 and 6.7.7	Water use could be managed to remain neutral but could also increase based on how produced waters and cooling water is managed It is conventional knowledge that CCS has larger mineral requirements than plants without CCS. However, some of these requirements may be met through low-cost or waste minerals. Moreover, there may be the potential for precipitated CaCO ₃ production through CO ₂ mineralisation (which is largely regarded as CCS and not CCU because of permanent storage). This was highlighted in IPCC SRCCL, p. 332, www.ipcc.ch/srccl/ . Thus, it may be synergy or tradeoff

Table 17.SM.2 | Chapter 7.

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Agriculture, forestry and other land use	Carbon sequestration in agriculture (soil carbon management in cropland and grasslands, agroforestry, biochar)	+ May lead to narrowing the yield gap, higher and stable profit due to increased productivity and reduced input use with benefit to soil fertility. Water management for reducing drought and adapting to climate change is important issue (<i>high confidence</i>)	+ Better and sustainable soil management will improve food production and availability as well. Water management for reducing drought and adapting to climate change is important issue (<i>high confidence</i>)	± Probably no direct impact (soil–human health nexus through nutritional transfer: may contribute to better nutrient security through quality and nutrient-rich products and better living if higher profits and diversified products) (<i>medium confidence</i>)			+ Better landscape water balance by influencing the quality and availability of water supply (<i>high confidence</i>)		+ Better soil management can lead to improved productivity and thus economic growth (<i>medium confidence</i>)				± Low environment footprints, quality and healthy food production and economic and social viability (<i>high confidence</i>)	+ Clear climate benefit (<i>high confidence</i>)	+ Better sponge function to life in water, and less nutrients into the water (<i>medium confidence</i>)	+ Proved beneficial for combating soil degradation and improving soil health and beneficial to biodiversity (<i>high confidence</i>)	+ Securing local food production and higher and stable profits may reduce migration and prevent conflict and support peace and justice (<i>medium confidence</i>)		Sections 7.3, 7.4 and 7.6	Almost not context or scale dependent. Low-cost option, high level of technology readiness. Difficulty in monitoring. Trade-offs with other uses of the organic matter
	Reduce CH ₄ and N ₂ O emissions in agriculture		± When part of improved agriculture, it may reduce hunger (<i>low confidence</i>)	+ Cleaner air and soil-plant-herbivore nexus (<i>high confidence</i>)			± Less use of water and less manure into water streams (<i>low confidence</i>)			± Requires innovative food production (<i>low confidence</i>)			+ Reduction of emissions (which is a part of responsible production) (<i>medium confidence</i>)	+ Clear reduction of emissions (<i>high confidence</i>)	+ Less impact on water (<i>high confidence</i>)	+ Less impact on land (<i>high confidence</i>)			Section 7.4	Risks include mitigation persistence, ecological impacts associated with improving feed quality and supply, or potential toxicity and animal welfare issues concerning feed additives
	Reduced conversion of forests and other ecosystems (deforestation, loss and degradation of peatlands and coastal wetlands)	± Protecting huge areas may lead to poverty (<i>medium confidence</i>)	– May lead to some competition for land (<i>medium confidence</i>)	+ Cleaner air, greener environment generally leads to better health (<i>high confidence</i>)			+ Better landscape water balance (<i>high confidence</i>)		± May lead to competition for land and less economic benefits (<i>medium confidence</i>)			± When surrounding cities, it may lead to cooling (<i>high confidence</i>)		+ Clear climate benefit (<i>high confidence</i>)	+ Better sponge function to life in water, and less nutrients into the water (<i>high confidence</i>)	+ Beneficial to biodiversity (<i>high confidence</i>)	± May lead to more competition for resources and thus pressures between actors (<i>medium confidence</i>)	± May lead to joint forces (<i>low confidence</i>)	Section 7.4	Many benefits in terms of climate and biodiversity. It can compete for land and thus with food provision
	Ecosystem restoration, reforestation, afforestation	+ If it provides income, food and wood products, then neutral to positive (<i>medium confidence</i>)	± May lead to competition for land when done at large scales. Reforestation and forest restoration can have co-benefits for food security (<i>medium confidence</i>)	+ Cleaner air, greener environment generally leads to better health (<i>medium confidence</i>)			± Better landscape water balance. Afforestation (on naturally unforested land) can compound climate-related risks to water security (<i>medium confidence</i>)		– May lead to competition for land and less economic benefits (<i>medium confidence</i>)		± When done with involvement of locals it can reduce inequality (<i>low confidence</i>)	+ When surrounding cities, it may lead to cooling (<i>high confidence</i>)		+ Clear climate benefit (<i>high confidence</i>)	+ Better sponge function to life in water when done in proper manner (<i>high confidence</i>)	+ Beneficial to biodiversity when done in proper manner (<i>medium confidence</i>)			Section 7.4	Very much context dependent and on how measures are carried out. If carried out at massive scale, competition for food will arise; when carried out adapted to local circumstances, and for various needs, the trade-offs are small; may have high opportunity costs
	Improved sustainable forest management	+ If it provides income and wood products, then neutral to positive (<i>high confidence</i>)	± If it provides income and wood products, then neutral to positive (<i>low confidence</i>)	+ Cleaner air, greener environment generally leads to better health (<i>low confidence</i>)			+ Better landscape water balance (<i>medium confidence</i>)	± Can lead to improved wood chain, including bioenergy from residues (<i>high confidence</i>)	+ If it provides income and wood products, then neutral to positive (<i>medium confidence</i>)	+ Can lead to improved wood chain, and biobased product innovation (<i>high confidence</i>)	± When done with involvement of locals it can reduce inequality (<i>low confidence</i>)	± Can lead to cooling of cities and building with biobased products (<i>medium confidence</i>)		+ Most likely climate benefit (<i>medium confidence</i>)	+ Better sponge function to life in water, and less nutrients into the water (<i>medium confidence</i>)	+ Beneficial to biodiversity (<i>high confidence</i>)			Section 7.4	This involves small changes in management of existing forests; effects per hectare are small. Can be beneficial for biodiversity, provision of wood, etc.
	Reduce food loss and food waste	+ Reduced food loss will reduce prices, and may lead to less poverty (<i>high confidence</i>)	+ Reduced food loss will reduce prices, and may lead to more food available (<i>high confidence</i>)	+ Reduced food loss will reduce prices, and may lead to more food available (<i>high confidence</i>)			+ Less use of water (<i>high confidence</i>)	+ Lead to less energy use (<i>high confidence</i>)			+ Balanced food distribution globally may reduce prices for many (<i>low confidence</i>)	+ Balanced food distribution globally may provide more sustainable societies (<i>low confidence</i>)	+ Balanced food distribution and reduced losses is part of responsible consumption (<i>high confidence</i>)	+ Clear reduction of emissions (<i>high confidence</i>)	+ Less impact on water (<i>medium confidence</i>)	+ Less impact on land (<i>high confidence</i>)	+ Leads to less competition for resources and thus less pressures between actors (<i>medium confidence</i>)		Section 7.5	Occurs in all societies, there are no trade-offs
	Shift to balanced, sustainable healthy diets	± Depends whether the healthier diet is cheaper, often not (<i>medium confidence</i>)	+ Balanced food distribution globally may reduce prices for many (<i>low confidence</i>)	+ Healthier diets for affluent populations (<i>high confidence</i>)			+ Less use of water (<i>high confidence</i>)	+ May lead to less energy use (<i>high confidence</i>)		± More innovative food production (<i>medium confidence</i>)	+ Balanced food globally may reduce prices for many (<i>low confidence</i>)	+ Balanced food globally may provide more sustainable societies (<i>low confidence</i>)	+ Clear reduction of emissions – Part of responsible production (<i>high confidence</i>)	+ Clear reduction of emissions (<i>high confidence</i>)	+ Less impact on water (<i>medium confidence</i>)	+ Less impact on land (<i>high confidence</i>)			Section 7.4	Only for affluent societies; synergies occur because it may lead to freeing up land
	Renewables supply timber, biomass, agri feedstock)	± Can lead to both positive and negative outcomes for livelihoods and food security; if it provides income, food and wood products, then neutral to positive (<i>medium confidence</i>)	± May lead to competition when done at large scale and not taking into account local circumstances or needs (<i>medium confidence</i>)	± Can lead to greener landscape, but can also result in large-scale undesirable changes (<i>medium confidence</i>)			± Can lead to better landscape-level water balance when done in proper manner (<i>medium confidence</i>)	± Can lead to better and more stable products and energy provision if done properly (<i>medium confidence</i>)	+ If it provides income and wood products, then neutral to positive (<i>medium confidence</i>)	+ Can lead to improved wood chain, and bio-based product innovation (<i>high confidence</i>)				± Clear reduction of emissions up to certain scales and volumes and when negative land-use effects are avoided (<i>high confidence</i>)	± Depending on type of land use, less impact on water (<i>medium confidence</i>)	± Depending on type of land use, less impact on life on land (<i>medium confidence</i>)			Section 7.6	Very much context dependent and dependent on how measures are carried out, leads to enhanced production of renewables needed for substitution of fossil based products. If done at massive scale and not adapted to local circumstances, then there are adverse implications for food security and livelihoods, and for biodiversity.

Table 17.SM.3 | Chapter 8.

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/ scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Urban systems	Urban land use and spatial planning	(+) Provides employment density and supports productivity (<i>high confidence</i>) (+) Can reduce exposure and vulnerability to climate change given policy integration (<i>high confidence</i>)	(+) Better spatial planning will reduce pressures on land use change, including croplands (<i>high confidence</i>) (–) Growth in urban extent can still reduce cropland if not sufficiently managed (<i>high confidence</i>)	(+) Improves access to health infrastructure; improves air quality when coupled to shifting energy use; improves wellbeing with green and blue infrastructure (<i>high confidence</i>)	(+) Better spatial planning increases educational opportunities (<i>medium confidence</i>)	(+) Can increase equal opportunities and effective participation of women, including urban governance (<i>medium confidence</i>)	(+) Can improve water quality, water-use efficiency, water harvesting and wastewater treatment; efficient urbanisation can also reduce GHG emissions from water infrastructure (<i>high confidence</i>)	(+) Can reduce energy use and enable access to modern energy infrastructure while urban infrastructure for energy services varies (<i>high confidence</i>)	(+) Provides employment density and supports productivity (<i>high confidence</i>)	(+) Sustainable urbanisation and settlement planning requires development across all infrastructure sectors (<i>high confidence</i>)	(+) Spatial inequalities within cities can be reduced; urban infrastructure gap between cities can be reduced (<i>high confidence</i>) (–) Unintended gentrification and spatial inequalities are still possible (<i>medium confidence</i>)	(+) Supports capacity for participatory, integrated and sustainable human settlement planning (Target 11.3) and protecting the poor and vulnerable (Target 11.5) (<i>high confidence</i>)	(+) Urbanisation with lower material demands will support responsible consumption and production (<i>high confidence</i>) (–) Urban population growth contributes to increased demand for resources with differences in scenarios; increase in urban water demand can increase pressures on water scarcity; over-exploitation of groundwater needs to be avoided (<i>medium confidence</i>)	(+) Contributes to both climate mitigation and adaptation given integration in urban planning (<i>high confidence</i>)	(+) Can reduce growth in urban expansion that can help protect coastal and marine ecosystems (<i>medium confidence</i>) (–) Urban development can still impact coastal and marine ecosystems (<i>medium confidence</i>)	(+) Can reduce growth in urban expansion that can help protect biodiversity on land and terrestrial and inland freshwaters (<i>high confidence</i>) (–) Urban development can still impact biodiversity (<i>medium confidence</i>)	(+) Has synergies with responsive, inclusive and participatory decision-making at all levels and transparent institutions (<i>medium confidence</i>)		Sections 8.2, 8.4 and 8.6	The impacts of the possible synergies and/or trade-offs with the SDGs will change according to the specific urban context. Synergies and/or trade-offs may be more significant in certain contexts than others. Urban mitigation with a view of the SDGs can support shifting pathways of urbanisation towards sustainability. The feasibility of urban mitigation options is also malleable and can increase with more enablers. Strengthened institutional capacity that also supports the scale and coordination of the mitigation options can increase these synergies.
	Electrification of the urban energy system	(+) Can address energy poverty that is linked to poverty; eradicating poverty is supported by access to modern energy services for all (<i>medium confidence</i>)	(+) Electrification can support welfare; electric stoves can support nutritional food intake (<i>medium confidence</i>) (–) Can have trade-offs if food systems are coupled with electricity and bioenergy (<i>medium confidence</i>)	(+) Improves air quality when coupled to shifting energy use as included in the option; Avoids air pollution from energy and transport infrastructure; Supports energy services for quality health services in hospitals (<i>high confidence</i>)	(+) Electrification and access to electricity supports quality education and educational attainment (<i>high confidence</i>)	(+) Supports equal opportunities, also through electricity for internet access if previously lacking (<i>medium confidence</i>)	(+) Renewable energy powered water treatment facilities can support clean water and sanitation (<i>medium confidence</i>)	(+) Supports renewable energy, energy efficiency and access to affordable, reliable and modern energy; renewable-energy generation technologies can enhance infrastructure resilience (<i>high confidence</i>)	(+) Supports technological upgrading, innovation and decent job creation (<i>high confidence</i>)	(+) Supports sustainable and resilient infrastructure and can support domestic technology development; renewable-energy generation technologies can enhance infrastructure resilience (<i>high confidence</i>)	(+) Supports equal opportunities, e.g. through internet access if previously lacking (<i>high confidence</i>)	(+) Supports adequate, safe and affordable housing as well as safe, affordable, accessible and sustainable transport (Targets 11.1 and 11.2) (<i>high confidence</i>)	(+) Allows leapfrogging to more resource-efficient urban development (<i>high confidence</i>) (–) Material demands of electrification technologies will increase; policies are important (<i>medium confidence</i>)	(+) Energy infrastructure can also strengthen climate resilience and adaptive capacity if addressed together (<i>medium confidence</i>)	(+) Energy systems can be designed to minimize impacts on water ecosystems (<i>medium confidence</i>)	(+) Clean energy will reduce the impacts of climate change on biodiversity and terrestrial ecosystems (<i>high confidence</i>) (–) Hydropower development and biofuel cultivation may impact ecosystems while there are multiple alternatives, e.g., use of degraded lands for solar energy farms (<i>medium confidence</i>)	(+) Improvement in governance through inclusive decision-making improves ability for energy systems to contribute to sustainable development (<i>medium confidence</i>)		Sections 8.2, 8.4 and 8.6	
	District heating and cooling networks	(+) Can address energy poverty that is linked to poverty; eradicating poverty is supported by access to modern energy services for all (<i>medium confidence</i>)	(–) Can have trade-offs if food systems are coupled with bioenergy and heat (<i>medium confidence</i>)	(+) Improves air quality when coupled to shifting energy use as included in the option; supports energy services for quality health services in hospitals (<i>medium confidence</i>)				(+) Supports renewable energy, energy efficiency and access to affordable, reliable and modern energy (<i>medium confidence</i>)	(+) Supports technological upgrading, innovation and decent job creation (<i>medium confidence</i>)	(+) Is being used to support sustainable and resilient infrastructure, including adaptation and mitigation (<i>medium confidence</i>)		(+) Supports capacity for participatory, integrated and sustainable human settlement planning (Target 11.3) (<i>high confidence</i>)	(+) Allows leapfrogging to more resource-efficient urban development (<i>medium confidence</i>)	(+) Energy infrastructure can also strengthen climate resilience and adaptive capacity if addressed together (<i>medium confidence</i>)		(+) Clean energy will reduce the impacts of climate change on biodiversity and terrestrial ecosystems (<i>high confidence</i>)	(+) Improvement in governance through inclusive decision-making improves ability for energy systems to contribute to sustainable development (<i>medium confidence</i>)		Sections 8.2, 8.4 and 8.6	
	Urban green and blue infrastructure	(+) Can increase employment and food security, e.g., urban agriculture (<i>high confidence</i>)	(+) Can increase employment and food security, e.g., urban agriculture (<i>medium confidence</i>)	(+) Better ecosystem services improve health and well-being, can improve air quality (<i>high confidence</i>)	(+) Urban green and blue infrastructure can increase opportunities and sites for environmental education (<i>medium confidence</i>)		(+) Also supports water-sensitive urban planning and protection of water-related ecosystems (<i>high confidence</i>)	(+) Produces a cooling effect, lowering energy use when in relative proximity (<i>medium confidence</i>)	(+) Can stimulate new green economies and green jobs (<i>medium confidence</i>)	(+) Supports sustainable and resilient infrastructure (<i>high confidence</i>)	(+) Can support equity given policy design (<i>medium confidence</i>) (–) Can push out low-income residents from main city areas without inclusive policy design (<i>medium confidence</i>)	(+) Supports air quality and universal access to safe, inclusive and accessible green and public spaces (Target 11.7) (<i>high confidence</i>)	(+) Supports sustainable development and lifestyles also ‘in harmony with nature’ as emphasised (Target 12.8) (<i>high confidence</i>)	(+) Contributes to both climate mitigation and adaptation given integration in urban planning (<i>high confidence</i>)	(+) Blue infrastructure can contribute to protecting coastal and marine ecosystems (<i>high confidence</i>)	(+) Enhances biodiversity within urban areas and ecosystem services (<i>high confidence</i>)	(+) Has synergies with responsive, inclusive and participatory decision-making at all levels and transparent institutions (<i>medium confidence</i>)		Sections 8.2, 8.4 and 8.6	
	Waste prevention, minimisation and management	(+) Can reduce informality in the waste sector and support poverty alleviation (<i>high confidence</i>)	(+) Can support reducing food waste in municipalities and urban centres (<i>medium confidence</i>)	(+) Better waste management improves air quality (<i>high confidence</i>) (–) Can depend on air pollution control techniques if waste incineration is involved (<i>medium confidence</i>)			(+) Improved water and wastewater infrastructure will reduce water pollution (<i>high confidence</i>)		(+) Can stimulate employment for value added products (<i>medium confidence</i>) (–) Transforming informality of waste recycling activities into programmes is important (<i>medium confidence</i>)	(+) Supports sustainable and resilient infrastructure (<i>high confidence</i>)		(+) Directly related to waste management; supports links between urban, peri-urban and rural areas (Target 11.a) (<i>high confidence</i>)	(+) Reduces waste generation through prevention, reduction, recycling and reuse (Target 12.5) (<i>high confidence</i>) (–) Waste segregation at source and waste processing facilities differ across context (<i>high confidence</i>)	(+) Reduces emissions through better management of urban waste in different contexts and is important for resilience, including coastal areas (<i>medium confidence</i>)	(+) Better waste management and wastewater treatment will protect coastal and marine ecosystems, reduce marine debris and nutrient pollution (<i>high confidence</i>)	(+) Better waste management and wastewater treatment will protect terrestrial and inland freshwaters (<i>high confidence</i>)	(+) Has synergies with responsive, inclusive and participatory decision-making at all levels and transparent institutions (<i>medium confidence</i>)		Sections 8.2 and 8.4, 8.6	
	Integrating sectors, strategies and innovations	(+) Increases employment density, reduces poverty and exposure and vulnerability to climate change (<i>high confidence</i>)	(+) Supports livelihoods, reduces pressures on croplands and consumption-related land-use impacts (<i>high confidence</i>)	(+) Improves access to health infrastructure; improves air quality when coupled to shifting energy use; improves wellbeing with green and blue infrastructure (<i>high confidence</i>)	(+) Can increase education opportunities, access to electricity and environmental education (<i>high confidence</i>)	(+) Can increase equal opportunities and effective participation of women, including urban governance (<i>medium confidence</i>)	(+) Can improve water quality, water-use efficiency, water harvesting and wastewater treatment; efficient urbanisation can also reduce GHG emissions from water infrastructure (<i>high confidence</i>)	(+) Supports renewable energy, energy efficiency and access to affordable, reliable and modern energy (<i>high confidence</i>)	(+) Supports technological upgrading, innovation and decent job creation (<i>high confidence</i>)	(+) Supports sustainable and resilient infrastructure (<i>high confidence</i>)	(+) Can reduce the urban infrastructure gap; sustainable urbanisation can support reducing inequality within and among cities; inclusivity of inhabitants in the informal sector is important (<i>high confidence</i>)	(+) Supports integrated policies and plans for inclusion, resource efficiency, mitigation and adaptation (Target 11.b) (<i>high confidence</i>)	(+) Allows leapfrogging to more resource-efficient urban development (<i>high confidence</i>)	(+) Contributes to both climate mitigation and adaptation, given integration in urban planning (<i>high confidence</i>)	(+) Can reduce growth in urban expansion that can help protect coastal and marine ecosystems (<i>medium confidence</i>)	(+) Can reduce growth in urban expansion that can help protect biodiversity on land and terrestrial and inland freshwaters (<i>high confidence</i>)	(+) Has synergies with responsive, inclusive and participatory decision-making at all levels and transparent institutions (<i>medium confidence</i>)	(+) Partnerships support sustainable infrastructure for urban areas; supports policy coherence for sustainable development (Target 17.14) (<i>high confidence</i>)	Sections 8.2 and 8.4, 8.6	

Table 17.SM.4 | Chapter 9.

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Buildings	Demand-side management	+ Reduce poverty due to less energy expenditures and other financial savings (<i>high confidence</i>)	+ Result in avoiding the 'heat or eat' dilemma (<i>low confidence</i>)	+ Improve health through better indoor air quality, fuel poverty alleviation, better ambient air quality, and reduction of the heat island effect. Furthermore, smart controllers and wireless communications that are used for controlling lighting, windows, HVAC equipment, water heaters, and other building equipment provide many other non-energy benefits such as improved security, access control, fire and other emergency detection and management, and on-time identification of maintenance issues (<i>high confidence</i>)			+ Lower energy demand can lead to reduced water demand for thermal cooling at energy production facilities (<i>medium confidence</i>)	+ Result in fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macroeconomic effects (GDP, employment, public budgets) associated with lower energy prices due to the reduced energy demand, energy efficiency investments, and fostering innovation. + Also result in improving labour productivity (<i>high confidence</i>)	+ Adoption of digitalisation, smart meters, etc., help in infrastructure improvement and expansion – Reduced energy demand can lead to early retirement of fossil energy infrastructure (<i>high confidence</i>)	+ Reduce income inequalities (<i>low confidence</i>)	+ Eliminate major sources (both direct and indirect) of poor air quality (indoor and outdoor) (<i>high confidence</i>)	+ Result in reduced consumption of natural resources (<i>medium confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)					Section 9.8 and Table 9.5	Economic impacts (synergies and trade-offs) are associated with reduced energy demand, resulting in lower energy prices, energy efficiency investments, fostering innovation, and improvements in labour productivity
	Highly energy-efficient building envelope	+ Reduce poverty due to less energy expenditures and other financial savings – The distributional costs of some mitigation policies supporting energy efficiency may reduce the disposable income of the poor (<i>medium confidence</i>)	+ Result in avoiding the 'heat or eat' dilemma (<i>low confidence</i>)	+ Improve health through better indoor air quality, fuel poverty alleviation, better ambient air quality, and reduction of the heat island effect. – Inadequate ventilation may lead to the sick building syndrome symptoms (<i>high confidence</i>)	+ Reduce school absenteeism due to better indoor conditions, while fuel poverty alleviation increases the available space at home for reading (<i>medium confidence</i>)		+ Lower energy demand can lead to reduced water demand for thermal cooling at energy production facilities (<i>medium confidence</i>)	+ Result in fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macroeconomic effects (GDP, employment, public budgets) associated with lower energy prices due to the reduced energy demand, energy efficiency investments, and fostering innovation + Also result in improving labour productivity (<i>high confidence</i>)	+ The development of 'green buildings' can foster innovation – Reduced energy demand can lead to early retirement of fossil energy infrastructure (<i>medium confidence</i>)	± Can reduce or increase income inequalities (<i>medium confidence</i>)	+ Eliminate major sources (both direct and indirect) of poor air quality (indoor and outdoor). Also, buildings with high energy efficiency and/or green features are sold/rented at higher prices than conventional, low-energy-efficient houses (<i>high confidence</i>)	+ Result in reduced consumption of natural resources (<i>medium confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)			+ Building retrofits are associated with lower crime; institutions that are effective, accountable and transparent are needed at all levels of government for boosting zero-energy buildings. (<i>medium confidence</i>)	+ The development of zero-energy buildings requires, among other things, capacity building and citizen participation, as well as monitoring of the achievements (<i>medium confidence</i>)	Section 9.8 and Table 9.5	Trade-offs related to public health may be minimised with adequate ventilation. Economic impacts (synergies and trade-offs) are associated with reduced energy demand, resulting in lower energy prices, energy efficiency investments, fostering innovation, and improvements in labour productivity
	Efficient heating, ventilation and air conditioning (HVAC)	+ Reduce poverty due to less energy expenditures and other financial savings – The distributional costs of some mitigation policies supporting energy efficiency may reduce the disposable income of the poor (<i>medium confidence</i>)	+ Result in avoiding the 'heat or eat' dilemma (<i>low confidence</i>)	+ Improve health through better indoor air quality, fuel poverty alleviation, better ambient air quality, and reduction of the heat island effect (<i>high confidence</i>)			+ Lower energy demand can lead to reduced water demand for thermal cooling at energy production facilities (<i>medium confidence</i>)	+ Result in fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macroeconomic effects (GDP, employment, public budgets) associated with lower energy prices due to the reduced energy demand, energy efficiency investments, and fostering innovation + Also result in improving labour productivity (<i>high confidence</i>)	+ The development of 'green buildings' can foster innovation – Reduced energy demand can lead to early retirement of fossil energy infrastructure (<i>medium confidence</i>)	± Can reduce or increase income inequalities (<i>medium confidence</i>)	+ Eliminate major sources (both direct and indirect) of poor air quality (indoor and outdoor) (<i>high confidence</i>)	+ Result in reduced consumption of natural resources (<i>medium confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)					Section 9.8 and Table 9.5	The distributional costs of some mitigation policies may hinder the implementation of these measures. In this case, appropriate access policies should be designed to efficiently shield poor households from the burden of carbon taxation Economic impacts (synergies and trade-offs) are associated with reduced energy demand, resulting in lower energy prices, energy efficiency investments, fostering innovation, and improvements in labour productivity
	Efficient appliances	+ Reduce poverty due to less energy expenditures and other financial savings – The distributional costs of some mitigation policies supporting energy efficiency may reduce the disposable income of the poor (<i>medium confidence</i>)	+ Result in avoiding the 'heat or eat' dilemma. Also, improved cookstoves provide better food security (<i>medium confidence</i>)	+ Improve health through better indoor air quality, fuel poverty alleviation, better ambient air quality, and reduction of the heat island effect (<i>high confidence</i>)	+ Reduce school absenteeism due to better indoor conditions, while fuel poverty alleviation increases the available space at home for reading (<i>medium confidence</i>)	+ Efficient cookstoves result in substantial time savings for women, thus increasing the time for rest, communication, education and productive activities (<i>medium confidence</i>)	+ Lower energy demand can lead to reduced water demand for thermal cooling at energy production facilities (<i>medium confidence</i>)	+ Result in energy/fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macroeconomic effects (GDP, employment, public budgets) associated with lower energy prices due to the reduced energy demand, energy efficiency investments, and fostering innovation + Also result in improving labour productivity (<i>high confidence</i>)	– Reduced energy demand can lead to early retirement of fossil energy infrastructure (<i>medium confidence</i>)	+ Efficient cookstoves result in substantial time savings for women and children, thus enhancing education and the development of productive activities (<i>medium confidence</i>)	+ Eliminate major sources (both direct and indirect) of poor air quality (indoor and outdoor) (<i>high confidence</i>)	+ Result in reduced consumption of natural resources – Possible risks due to the penetration of new, efficient appliances and early retirement of existing equipment (<i>medium confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)		+ Result in halting deforestation through efficient cookstoves (<i>medium confidence</i>)			Section 9.8 and Table 9.5	Under real-world conditions improved cookstoves have shown smaller, and in many cases limited, long-run health and environmental impacts than expected, as the households use these stoves irregularly and inappropriately, fail to maintain them, and their usage declines over time. It is of paramount importance for the various cookstove programmes to consider the mid- and long-term needs of maintenance, repair, or replacement to support their sustained use. In addition, the distributional costs of some mitigation policies may hinder the implementation of these measures. In this case, appropriate access policies should be designed to efficiently shield poor households from the burden of carbon taxation. Economic impacts (synergies and trade-offs) are associated with reduced energy demand, resulting in lower energy prices, energy efficiency investments, fostering innovation, and improvements in labour productivity and energy access

Table 17.SM.4 | Chapter 9 (continued).

		Sustainable Development Goals																		
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/scale)
Buildings	Building design and performance	+ Reduce poverty due to less energy expenditures and other financial savings (<i>medium confidence</i>)	+ Result in avoiding the 'heat or eat' dilemma. Also, green surfaces and urban farming (vertical, basement or unused buildings) contribute to local and resilient food production (<i>medium confidence</i>)	+ Improve health through better indoor air quality, fuel poverty alleviation, better ambient air quality, and reduction of the heat island effect (<i>high confidence</i>)			+ Lower energy demand can lead to reduced water demand for thermal cooling at energy production facilities. Also, these measures result in water savings due to improved indoor conditions and lower space of dwellings (<i>medium confidence</i>)	+ Result in fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macro-economic effects (GDP, employment, public budgets) associated with lower energy prices due to the reduced energy demand (<i>high confidence</i>)	– Reduced energy demand can lead to early retirement of fossil energy infrastructure (<i>medium confidence</i>)	+ Reduce income inequalities (<i>low confidence</i>)	+ Eliminate major sources (both direct and indirect) of poor air quality (indoor and outdoor) (<i>high confidence</i>)	+ Result in reduced consumption of natural resources (<i>medium confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)		+ Green roofs and walls strengthen urban biodiversity (<i>medium confidence</i>)	+ Institutions that are effective, accountable and transparent are needed at all levels of government for boosting sufficiency measures (<i>medium confidence</i>)		Section 9.8 and Table 9.5	Economic impacts (synergies and trade-offs) are mainly associated with reduced energy demand and the resulting in lower energy prices
	On-site and nearby production and use of renewables	+ Increase the productive time of women and children – The distributional costs of some mitigation policies supporting RES (renewables) may reduce the disposable income of the poor (<i>medium confidence</i>)	+ Improving energy access enhances agricultural productivity and improves food security – Increased bioenergy production may restrict the available land for food production (<i>medium confidence</i>)	+ Improve health through better indoor air quality, energy/fuel poverty alleviation, better ambient air quality, and reduction of the heat island effect (<i>high confidence</i>)	+ Reduce school absenteeism due to better indoor conditions and enable people living in poor developing countries to read (<i>medium confidence</i>)	+ Improved access to electricity and clean fuels in developing countries will result in substantial time savings for women, thus increasing the time for rest, communication, education and productive activities (<i>medium confidence</i>)	+ Substituting fossil-fuelled electricity can lead to reduced water demand for thermal cooling at energy production facilities. Also, improved access to electricity is necessary to treat water in homes – Switch to bioenergy may increase water use compared to existing conditions (<i>medium confidence</i>)	+ Result in energy poverty alleviation and improving the security of energy supply – Risks of reduced energy access, in cases where the distributional costs of mitigation increase the energy costs (<i>medium confidence</i>)	± Result in direct and indirect macro-economic effects (GDP, employment, public budgets) associated with lower energy prices due to the reduced energy demand, RES investments, improved energy access and fostering innovation (<i>high confidence</i>)	+ Adoption of RES and smart grids helps in infrastructure improvement and expansion – Increased RES penetration can lead to early retirement of fossil energy infrastructure (<i>high confidence</i>)	± Can reduce or increase income inequalities + Improved access to electricity and clean fuels in developing countries will result in substantial time savings for women and children, enhancing education and the development of productive activities (<i>medium confidence</i>)	+ Eliminate major sources (both direct and indirect) of poor air quality (indoor and outdoor) (<i>high confidence</i>)	+ Result in reduced consumption of natural resources (<i>medium confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)		+ Result in halting deforestation through improved access to electricity and clean fuels (<i>medium confidence</i>)	+ Improved access to electric lighting can improve safety (particularly for women and children) + Institutions that are effective, accountable and transparent are needed at all levels of government for providing energy access and promoting modern renewables (<i>medium confidence</i>)	+ The development of zero energy buildings requires, among other things, capacity building and citizen participation, as well as monitoring of the achievements (<i>medium confidence</i>)	Section 9.8 and Table 9.5	The distributional costs of some mitigation policies supporting RES may reduce the disposable income of the poor and hinder their utilisation. In this case, appropriate access policies should be designed to efficiently shield poor households from the burden of carbon taxation. Some of the trade-offs are mainly related to the switch to bioenergy, which may restrict the available land for food production and increase water consumption Economic impacts (synergies and trade-offs) are associated with reduced demand for fossil fuels, resulting in lower energy prices, RES investments, fostering innovation, and improvements in energy access
	Change in construction methods and circular economy			+ Improve health through better labour conditions (<i>medium confidence</i>)			± The change in construction methods and the development of circular business models can lead to reduced or increased water demand, as a trade-off (<i>medium confidence</i>)	+ Result in energy/fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macro-economic effects (GDP, employment, public budgets) associated with development of smarter construction methods and circular business models + Also result in improving labour productivity (<i>high confidence</i>)	+ The development of smarter construction methods and circular business models can foster innovation (<i>high confidence</i>)		+ Result in reduced consumption of natural and scarce resources, waste generation and environmental impacts (<i>high confidence</i>)	+ Result in reduced consumption of natural and scarce resources (<i>high confidence</i>)	+ Reduce emissions and increase resilience (<i>high confidence</i>)			+ The change in construction methods and the development of circular business models requires a better integration and partnership between stakeholders (<i>high confidence</i>)		Sections 9.4 and 9.5	Economic impacts (synergies and trade-offs) are associated with development of smarter construction methods, circular business models, and improvements in labour productivity
	Change in construction materials			+ Bio-based and natural materials, e.g., raw earth, can improve indoor air quality and brings the concept of biophilia – Bio-based and natural materials can be more susceptible to the appearance of biological organisms that can cause health problems (<i>medium confidence</i>)			± The change in construction materials can lead to reduced or increased water demand, as a trade-off (<i>medium confidence</i>)	+ Result in energy/fuel poverty alleviation and improving the security of energy supply (<i>high confidence</i>)	± Result in direct and indirect macro-economic effects (GDP, employment, public budgets) associated with the use and development of green construction materials (<i>medium confidence</i>)	+ The use and development of green construction materials can foster innovation (<i>high confidence</i>)		+ Result in reduced consumption of natural and scarce resources, waste generation and environmental impacts (<i>high confidence</i>)	+ Result in reduced consumption of natural and scarce resources (<i>high confidence</i>)	+ Reduce emissions, removal and storage of CO ₂ (bio-based materials) and increase resilience (<i>high confidence</i>)		– Bio-based materials can increase the pressure and competition for land use (<i>medium confidence</i>)		+ The change in construction materials requires a better integration and partnership between stakeholders (<i>high confidence</i>)		Section 9.4

Table 17.SM.5 | Chapter 10.

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/ scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Transport	Fuel efficiency-light duty vehicle	+ Improved efficiency reduces costs and makes transport more affordable (<i>high confidence</i>)	± Land use for wind energy needs to be coordinated based on local circumstances, otherwise can have negative implications on food security (<i>medium confidence</i>)	+ Reduce air pollution/improve air quality (<i>high confidence</i>)				+ Can support the global rate of improvement in overall energy efficiency (<i>high confidence</i>)	+ Creation of new jobs due to new investment in fuel efficiency (<i>medium confidence</i>)			+ Can reduce air pollution in cities (<i>high confidence</i>)		+ Reduction of GHG emissions (<i>high confidence</i>)		+ Reduce demand for land needed to produce transportation fuels (<i>medium confidence</i>)			Sections 10.3, 10.4 and 10.8	Increased demand for electricity for EVs and production of hydrogen and derivatives requires careful integration with the power sector. For example, increased demand for renewable electricity could pose additional land-use constraints. Simultaneously, smart charging of EVs can support the grid integration of renewables. Similarly, hydrogen production could be scheduled to manage the variability of wind and solar. Competition for hydrogen with other sectors should also be considered. Synergies and/or trade-offs may be more significant in certain contexts than others. Strengthened institutional capacity that also supports the scale and coordination of the mitigation options can increase these synergies
	Electric light-duty vehicles (LDVs)		± Land use for solar energy needs to be coordinated based on local circumstances, otherwise can have negative implications on food security (<i>medium confidence</i>)	± Battery electric vehicles (BEVs) have no tailpipe emissions, which further offsets the increased PM emissions from road and tyre wear. BEVs are generally heavier than their ICEV counterparts, which may potentially cause higher stress on the road surfaces and tyres, with consequently higher PM emissions per kilometre driven (<i>high confidence</i>)				+ EVs consume considerably less energy than conventional fuels, which increases affordability (<i>high confidence</i>) ± EVs can positively or negatively impact electric grid functioning depending on charging behaviour and grid integration strategy (<i>high confidence</i>)	+ Could create jobs associated with the EV supply chain + Could create jobs to build and operate the associated infrastructure (<i>low confidence</i>)	+ Larger penetration of electric vehicles requires innovative business models; n Digitalisation and automatic vehicle will help on the socio-economic structures that impede adoption of EVs and the urban structures that enable reduced car dependence; there is a need for investments in the infrastructure that can support alternative fuels for LDVs. Large-scale electrification of LDVs requires expansion of low-carbon power systems, while charging or battery swapping infrastructure is needed for some segments (<i>high confidence</i>)	± Significant equity issues with EVs in the transition period can be overcome with programmes, for example, by expanding public charging infrastructure (<i>medium confidence</i>)	+ Can reduce air and noise pollution in cities (<i>high confidence</i>)	± Could increase demand for critical minerals but increased recycling can mitigate this risk (<i>medium confidence</i>)	+ Reduction of GHG emissions (<i>high confidence</i>)					Sections 10.3, 10.4 and 10.8	
	Shift to public transport	+ Affordable transport access for all + Improve access to health, education, and other social services lowering the cost of services needed by the low-income/poor (<i>high confidence</i>)	± Farm employment and incomes could increase, which is a key component of SDG 2 (2.3 to be specific). The reason for the trade-off is competition between food and bioenergy crops (<i>medium confidence</i>)	+ Access to healthcare; reduce air pollution/increase air quality (<i>high confidence</i>)	+ Affordable public transport can increase access to educational resources (<i>high confidence</i>)	+ Affordable transport access for all (<i>high confidence</i>)		+ Improves energy efficiency of transport and makes it more affordable (<i>high confidence</i>)	+ Role of transport for economic and human development (<i>high confidence</i>)	± Needs adequate infrastructure; in developing countries weather conditions and unreliable connectivity affect the lack of incentives to improve existing public transportation (<i>high confidence</i>)	+ Improved investments in public transit increase equity in transport access (<i>high confidence</i>)	+ Sustainable transport systems for cities; facilitates universal access to public transport (<i>high confidence</i>) + Could support positive economic links between urban and peri-urban areas (<i>high confidence</i>) + Can reduce air pollution in cities (<i>high confidence</i>)	+ Reduced material consumption during production of vehicles and their operations (<i>high confidence</i>)	+ Reduction of GHG emissions (<i>high confidence</i>)					Sections 10.2 and 10.8, Table 10.3	
	Shift to bikes, ebikes and non motorised transport	+ Affordable transport access for all + Improve access to health, education, and other social services, lowering the cost of services needed by the low-income/poor (<i>high confidence</i>)	± Could lead to fisheries damage if not properly managed (<i>medium confidence</i>)	± Reduce air pollution; increases physical activity leading to reduced health mortality – Traffic crashes discourage the use of bikes + Scaling up active modes (through careful local urban design and transport planning) can reduce gender inequities in access to basic services, healthcare and education (<i>medium confidence</i>)	+ Scaling up active modes (through careful local urban design and transport planning) can reduce gender inequities in access to basic services, healthcare and education (<i>medium confidence</i>)	+ Scaling up active modes (through careful local urban design and transport planning) can reduce gender inequities in access to basic services (<i>medium confidence</i>)		+ Saves energy (<i>high confidence</i>)	+ Increases employment opportunities, demand for bike repair shops, bike parking (<i>medium confidence</i>)	+ Needs adequate infrastructure + Opportunities including digitalisation, the Internet of Things and also 'big data' (<i>high confidence</i>)	+ Access to bicycle lanes or cycle tracks increases the odds of female commuters using bicycles (<i>medium confidence</i>)	+ Compact, polycentric cities where active transport is most viable can enhance inclusive and sustainable urbanisation (<i>high confidence</i>) + Can reduce air pollution in cities (<i>high confidence</i>)	+ Reduced material consumption during production of vehicles and their operations (<i>high confidence</i>)	+ Reduction of GHG emissions (<i>high confidence</i>)		+ Preserve land that would have been otherwise used to construct and maintain parking garages and surface parking lots (<i>medium confidence</i>)			Sections 10.2 and 10.8, Table 10.3	
	Fuel efficiency-heavy duty vehicle	+ Improved efficiency reduces costs and makes transport more affordable (<i>high confidence</i>)		+ Reduce air pollution/improve air quality (<i>high confidence</i>)	+ Improved efficiency reduces costs and makes transport more affordable (<i>high confidence</i>)			+ Can support the global rate of improvement in overall energy efficiency (<i>high confidence</i>)	+ Creation of new jobs due to new investment in fuel efficiency (<i>medium confidence</i>)					+ Reduction of GHG emissions (<i>high confidence</i>)		+ Reduce demand for land needed to produce transportation fuels (<i>medium confidence</i>)			Sections 10.3, 10.4 and 10.8	

Table 17.SM.5 | Chapter 10 (continued).

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/ scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Transport	Fuel shift (including electricity)-heavy duty vehicles (HDVs)			+ Reduce air pollution/improve air quality (<i>medium confidence</i>)				+ Some alternative fuels can help increase the share of renewable energy in the global energy mix (<i>medium confidence</i>)	+ Could create jobs associated with the supply chain of new fuels + Could create jobs to build and operate the associated infrastructure (<i>low confidence</i>)	+ R&D is critical for new fuels and to test the full life cycle costs of various heavy vehicle options; need to invest in supporting infrastructure (<i>high confidence</i>)			± Electric vehicles (EVs) and fuel cell vehicles (FCVs) for HDVs could increase demand for critical minerals but increased recycling can mitigate this risk (<i>medium confidence</i>)	+ Reduction of GHG emissions (<i>high confidence</i>)					Sections 10.3, 10.4 and 10.8	Increased demand for electricity for EVs and production of hydrogen and derivatives requires careful integration with the power sector. For example, increased demand for renewable electricity could pose additional land-use constraints. Simultaneously, smart charging of EVs can support the grid integration of renewables. Similarly, hydrogen production could be scheduled to manage the variability of wind and solar. Competition for hydrogen with other sectors should also be considered. Synergies and/or trade-offs may be more significant in certain contexts than others. Strengthened institutional capacity that also supports the scale and coordination of the mitigation options can increase these synergies
	Shipping efficiency, logistics optimisation, new fuels							+ Some alternative fuels can help increase the share of renewable energy in the global energy mix (<i>medium confidence</i>) + Can support the global rate of improvement in over-all energy efficiency (<i>medium confidence</i>)	+ Could create jobs associated with the supply chain of new fuels + Could create jobs to build and operate the associated infrastructure (<i>low confidence</i>)	+ R&D is critical for new fuels and to test the full life cycle costs of various heavy vehicle options; need to invest in supporting infrastructure (<i>high confidence</i>)				+ Reduction of GHG emissions (<i>high confidence</i>)					Sections 10.6 and 10.8	
	Aviation-energy efficiency, new fuels							+ Some alternative fuels can help increase the share of renewable energy in the global energy mix (<i>medium confidence</i>) + Can support the global rate of improvement in over-all energy efficiency (<i>medium confidence</i>)	+ Could create jobs associated with the supply chain of new fuels + Could create jobs to build and operate the associated infrastructure (<i>low confidence</i>)	+ R&D is critical for new fuels and to test the full life cycle costs of various heavy vehicle options; need to invest in supporting infrastructure (<i>high confidence</i>)				+ Reduction of GHG emissions (<i>high confidence</i>)					Sections 10.5 and 10.8	
	Biofuels		– Using land to produce biofuels could put stress on global food systems + Could increase incomes for farmers and support investments in rural infrastructure (<i>medium confidence</i>)	± Biofuels may improve air quality due to reductions in tailpipe emissions of some pollutants. The biofuels supply chain may negatively impact air quality (e.g., due to increased fertiliser use) (<i>medium confidence</i>)				+ Can help increase the share of renewable energy in the global energy mix (<i>high confidence</i>)	+ Could create jobs associated with the supply chain of biofuels + Could create jobs to build and operate the associated infrastructure (<i>low confidence</i>)	+ R&D is critical for new fuels and to test the full life cycle costs of various heavy vehicle options; need to invest in supporting infrastructure (<i>high confidence</i>)		+ Could reduce air pollution in cities (<i>medium confidence</i>)		+ Reduction of GHG emissions (<i>high confidence</i>)	± Could increase eutrophication in water bodies (<i>high confidence</i>)	± Additional land use for biofuels may increase pressure on biodiversity (<i>high confidence</i>)			Sections 10.3, 10.4, 10.5, 10.6 and 10.8	

Table 17.SM.6 | Chapter 11.

		Sustainable Development Goals																	Line of sight (section numbers, tables, figures, box)	Remarks (context specificity/scale)
Sector	Sectoral mitigation options	 SDG 1 End poverty	 SDG 2 Zero hunger	 SDG 3 Good health and wellbeing	 SDG 4 Quality education	 SDG 5 Gender equality	 SDG 6 Clean water and sanitation	 SDG 7 Affordable and clean energy	 SDG 8 Decent work and economic growth	 SDG 9 Industry, innovation and infrastructure	 SDG 10 Reduced inequalities	 SDG 11 Sustainable cities and communities	 SDG 12 Responsible consumption and production	 SDG 13 Climate action	 SDG 14 Life below water	 SDG 15 Life on land	 SDG 16 Peace, justice and strong institutions	 SDG 17 Partnership		
Industry	Energy efficiency			+ Reduce air pollution (<i>medium confidence</i>)				+ Enhances security in clean energy (<i>high confidence</i>)	+ Employment opportunities in a green economy (<i>high confidence</i>)	+ Industrial innovation through new technologies (<i>high confidence</i>)				+ Contributes to climate action through efficient use of energy (<i>high confidence</i>)					Section 11.5.3	Heavily dependent on technology and so the scale of the continuous co-benefits across regions would depend on the extent and ease of technological transfer
	Material efficiency and demand reduction						+ Reduce the pressures on water bodies (<i>low confidence</i>)		+ New Business Models generate employment opportunities (<i>medium confidence</i>) – Reduction in national sales tax revenue in medium term (<i>low confidence</i>)	+ Infrastructural development to support mitigation option (<i>medium confidence</i>)			+ Environmental stewardship (<i>medium confidence</i>)	+ Contributes to climate action through reduced consumption (<i>high confidence</i>)					Section 11.5.3	The scale of the co-benefits achieved through material efficiency would depend on the extent to which the transition from traditional to requisite new business models can be achieved
	Circular material flows			+ Reduce air pollution (<i>medium confidence</i>)			+ Increase use of waste as resource (<i>high confidence</i>)	+ Improved energy efficiency as key CE practice (<i>medium confidence</i>)	+ Job opportunities through new business models (<i>medium confidence</i>)			+ Public environmental awareness (<i>medium confidence</i>)	+ Enhances environmental benefits + Increase use of waste as resource (<i>high confidence</i>)		+ Studies reported direct relationship between CE and SDG 14 (<i>high confidence</i>)	+ Enhances biodiversity protection on land (<i>low confidence</i>)		+ Improved social relations between industrial sectors and local societies (<i>medium confidence</i>)	Section 11.5.3	Successful implementation of transformational new business models is required to scale up and derive extended co-benefits through the CE strategy
	Electrification	+ Supports poverty alleviation strategies (<i>high confidence</i>)	+ Improved food security – Fuel switching to options such as biomass and bioenergy can have negative impact on food prices (<i>medium confidence</i>)	+ Supports delivery of health services + Improves indoor air quality compared to biomass use (<i>high confidence</i>)		+ Reduces energy-related hurdles domestically affecting women (<i>high confidence</i>)		+ Decarbonisation of grid when fuel is switched to cleaner sources (<i>high confidence</i>)	+ Increased economic activity and employment (<i>high confidence</i>)					+ Contributes to climate action through switching to renewables (<i>high confidence</i>)		– Negative impact on SDG 15 [fuel switching to options such as biomass and bioenergy] (<i>high confidence</i>)			Sections 11.5.3 and 6.7.7	The extent of the co-benefits experience on social system would be relative as it would be dependent on their current access to energy
	CCS and carbon capture and utilisation (CCU)			+ Control of non-CO ₂ pollutants (such as sulphur dioxide) – increase of non-CO ₂ pollutants (such as particulate matter, nitrogen oxide and ammonia) (<i>high confidence</i>)			– Deployment of CCS and CCU would require increased water consumption (<i>high confidence</i>)	+ Decarbonisation of energy production through utilisation of CO ₂ (<i>high confidence</i>) – Deployment of CCS and CCU would require high energy demand (<i>high confidence</i>)	+ Diversified employment prospects (<i>low confidence</i>)	+ Direct foreign investment and know-how (<i>medium confidence</i>)		+ Deployment of CCS and CCU would contribute to enhancing the sustainability of cities (<i>high confidence</i>)		+ Contributes to climate action through carbon capture (<i>high confidence</i>)		– Deployment of CCS and CCU would require additional land use (<i>high confidence</i>)			Section 11.5.3	15–25% additional energy is required by CCS technologies compared with conventional plants. As such, this has potential implications for air pollutants. If no additional measures to reduce emissions are installed, particulate matter, nitrogen oxide and ammonia would increase accordingly

Annexes

Annex I: Glossary

Coordinating Editors:

Renée van Diemen (the Netherlands/United Kingdom), J.B. Robin Matthews (France/United Kingdom), Vincent Möller (Germany), Jan S. Fuglestad (Norway), Valérie Masson-Delmotte (France), Carlos Méndez (Venezuela), Andy Reisinger (New Zealand), Sergey Semenov (the Russian Federation)

Editorial Team:

Elin Lerum Boasson (Norway), Antonette Castaneda (Guatemala), Lazarus Chapungu (Zimbabwe), Lilia Caiado Couto (Brazil), Annette Cowie (Australia), Nandini Das (India), El Hdaji Mbaye Madien Diagne (Senegal), Oliver Geden (Germany), James S. Gerber (the United States of America), Siyue Guo (China), Shan Hu (China), Kiane de Kleijne (the Netherlands), Michael König (Germany), David Simon Lee (United Kingdom), Andreas Löschel (Germany), André F.P. Lucena (Brazil), Eduardo Miranda Casseres (Brazil), Jacqueline Peel (Australia), Patricia E. Perkins (Canada), Priyadarshi Shukla (India), Jim Skea (United Kingdom), Brent Sohngen (the United States of America), Enock Ssekuubwa (Uganda), Linda Steg (the Netherlands)

Note:

This glossary defines some specific terms as the Lead Authors intend them to be interpreted in the context of this report. Italicised words in definitions indicate that the italicised term is defined in the Glossary.

Subterms appear in *italics* beneath main terms.

This chapter should be cited as:

IPCC, 2022: Annex I: Glossary [van Diemen, R., J.B.R. Matthews, V. Möller, J.S. Fuglestad, V. Masson-Delmotte, C. Méndez, A. Reisinger, S. Semenov (eds)]. In IPCC, 2022: *Climate Change 2022: Mitigation of Climate Change. Contribution of Working Group III to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* [P.R. Shukla, J. Skea, R. Slade, A. Al Khourdajie, R. van Diemen, D. McCollum, M. Pathak, S. Some, P. Vyas, R. Fradera, M. Belkacemi, A. Hasija, G. Lisboa, S. Luz, J. Malley, (eds.)]. Cambridge University Press, Cambridge, UK and New York, NY, USA. doi: 10.1017/9781009157926.020

1.5°C pathway See *Pathways*.

Acceptability of policy or system change The extent to which a policy or system change is evaluated unfavourably or favourably, or rejected or supported, by members of the general public (public acceptability) or politicians or governments (political acceptability). Acceptability may vary from totally unacceptable/fully rejected to totally acceptable/fully supported; individuals may differ in how acceptable policies or system changes are believed to be.

Access to modern energy services Access to clean, reliable and affordable energy services for cooking, heating, lighting, communications, and productive uses.

Adaptation In *human systems*, the process of adjustment to actual or expected *climate* and its effects, in order to moderate harm or exploit beneficial opportunities. In natural systems, the process of adjustment to actual *climate* and its effects; human intervention may facilitate adjustment to expected climate and its effects. See also *Adaptation options*, *Adaptive capacity*, and *Maladaptive actions (Maladaptation)*.

Adaptation limits

The change in climate where adaptation is unable to prevent damaging impacts and further risk. Soft limits occur when additional adaptation may be possible if constraints are able to be overcome. Hard limits occur when no additional adaptation is possible.

Incremental adaptation

Adaptation that maintains the essence and integrity of a system or process at a given scale (Park et al. 2012). In some cases, incremental adaptation can accrue to result in transformational adaptation (Tàbara et al. 2019; Termeer et al. 2017). Incremental adaptations to change in climate are understood as extensions of actions and behaviours that already reduce the losses or enhance the benefits of natural variations in extreme weather/climate events.

Transformational adaptation

Adaptation that changes the fundamental attributes of a social-ecological system in anticipation of climate change and its impacts.

Adaptation options The array of strategies and measures that are available and appropriate for addressing *adaptation*. They include a wide range of actions that can be categorised as structural, *institutional*, ecological or behavioural.

Adaptation pathways See *Pathways*.

Adaptive capacity The ability of systems, *institutions*, humans and other organisms to adjust to potential damage, to take advantage of opportunities, or to respond to consequences (MA 2005).

Adaptive governance See *Governance*.

Additionality The property of being additional. Mitigation is additional if the *greenhouse gas* emission reductions or removals would not have occurred in the absence of the associated policy intervention or activity.

[Note: Additionality is one of several key criteria used to ensure the environmental integrity of *Offsets (in climate change mitigation)*].

See also *Greenhouse gas emission metric*.

Adverse side-effect A negative effect that a policy or measure aimed at one objective has on another objective, thereby potentially reducing the net benefit to society or the environment. See also *Co-benefits*, *Risk*, and *Trade-off*.

Aerosol A suspension of airborne solid or liquid particles, with typical particle size in the range of a few nanometres to several tens of micrometres and atmospheric lifetimes of up to several days in the troposphere and up to years in the stratosphere. The term aerosol, which includes both the particles and the suspending gas, is often used in this report in its plural form to mean 'aerosol particles'. Aerosols may be of either natural or anthropogenic origin in the troposphere; stratospheric aerosols mostly stem from volcanic eruptions. Aerosols can cause an effective radiative forcing directly through scattering and absorbing radiation (aerosol–radiation interaction), and indirectly by acting as cloud condensation nuclei or ice nucleating particles that affect the properties of clouds (aerosol–cloud interaction), and upon deposition on snow- or ice-covered surfaces. Atmospheric aerosols may be either emitted as primary particulate matter or formed within the atmosphere from gaseous precursors (secondary production). Aerosols may be composed of sea salt, organic carbon, black carbon (BC), mineral species (mainly desert dust), sulphate, nitrate and ammonium or their mixtures. See also *Short-lived climate forcers (SLCFs)*.

Afforestation Conversion to *forest* of land that historically has not contained forests.

[Note: For a discussion of the term *forest* and related terms such as *afforestation*, *reforestation* and *deforestation*, see the 2006 IPCC Guidelines for National Greenhouse Gas Inventories and their 2019 Refinement, and information provided by the *United Nations Framework Convention on Climate Change* (IPCC 2006, 2019; UNFCCC 2021a,b).]

See also *Deforestation*, *Reducing Emissions from Deforestation and Forest Degradation (REDD+)*, *Reforestation*, *Anthropogenic Removals*, and *Carbon dioxide removal (CDR)*.

Agreement In this report, the degree of agreement within the scientific body of knowledge on a particular finding is assessed based on multiple lines of *evidence* (e.g., mechanistic understanding, theory, data, models, expert judgement) and expressed qualitatively (Mastrandrea et al. 2010). See also *Confidence*, *Likelihood*, and *Uncertainty*.

Agriculture, Forestry and Other Land Use (AFOLU) In the context of national *greenhouse gas (GHG)* inventories under the *United Nations Framework Convention on Climate Change (UNFCCC)*, AFOLU is the sum of the GHG inventory sectors Agriculture and Land Use, Land-Use Change and Forestry (LULUCF); see the 2006 IPCC Guidelines for National GHG Inventories for details. Given the difference in estimating the 'anthropogenic' *carbon dioxide (CO₂)* removals between countries and the global modelling community, the land-related net GHG emissions from global models included in this report are not necessarily directly comparable with LULUCF estimates in national GHG Inventories. See also *Land use*, *Land-use change and forestry (LULUCF)* and *Land-use change (LUC)*.

Agroecology The science and practice of applying ecological concepts, principles and knowledge (i.e., the interactions of, and explanations for, the diversity, abundance and activities of organisms) to the study, design and management of sustainable agroecosystems.

It includes the roles of human beings as a central organism in agroecology by way of social and economic processes in farming systems. Agroecology examines the roles and interactions among all relevant biophysical, technical and socio-economic components of farming systems and their surrounding landscapes (IPBES 2019).

Air pollution Degradation of air quality with negative effects on human health or the natural or built environment due to the introduction, by natural processes or human activity, into the *atmosphere* of substances (gases, *aerosols*) which have a direct (primary pollutants) or indirect (secondary pollutants) harmful effect. See also *Short-lived climate forcers (SLCFs)*.

Albedo The proportion of sunlight (solar radiation) reflected by a surface or object, often expressed as a percentage. Clouds, snow and ice usually have high albedo; soil surfaces cover the albedo range from high to low; vegetation in the dry season and/or in arid zones can have high albedo, whereas photosynthetically active vegetation and the ocean have low albedo. The Earth's planetary albedo changes mainly through changes in cloudiness and of snow, ice, leaf area and *land cover*.

Anomaly The deviation of a variable from its value averaged over a *reference period*.

Anthropogenic Resulting from or produced by human activities.

Anthropogenic emissions Emissions of *greenhouse gases (GHGs)*, *precursors* of GHGs and *aerosols* caused by human activities. These activities include the burning of *fossil fuels*, *deforestation*, *land use and land-use changes (LULUC)*, livestock production, fertilisation, waste management, and industrial processes. See also *Anthropogenic* and *Anthropogenic removals*.

Anthropogenic removals The withdrawal of *greenhouse gases (GHGs)* from the *atmosphere* as a result of deliberate human activities. These include enhancing biological sinks of CO₂ and using chemical engineering to achieve long-term removal and storage. *Carbon capture and storage (CCS)*, which alone does not remove CO₂ from the atmosphere, can help reduce atmospheric CO₂ from industrial and energy-related sources if it is combined with bioenergy production (*BECCS*), or if CO₂ is captured from the air directly and stored (*DACCS*).

[Note: In the 2006 IPCC Guidelines for National GHG Inventories (IPCC 2006), which are used in reporting of emissions to the UNFCCC, 'anthropogenic' land-related GHG fluxes are defined as all those occurring on 'managed land', i.e., 'where human interventions and practices have been applied to perform production, ecological or social functions'. However, some removals (e.g., removals associated with CO₂ fertilisation and N deposition) are not considered as 'anthropogenic', or are referred to as 'indirect' anthropogenic effects, in some of the scientific literature assessed in this report. As a consequence, the land-related net GHG emission estimates from global models included in this report are not necessarily directly comparable with LULUCF estimates in national GHG Inventories.]

See also *Carbon dioxide removal (CDR)*, *Afforestation*, *Biochar*, *Enhanced weathering*, *Ocean alkalisation/Ocean alkalinity enhancement*, *Reforestation*, and *Soil carbon sequestration (SCS)*.

Atmosphere The gaseous envelope surrounding the Earth, divided into five layers – the troposphere which contains half of the Earth's

atmosphere, the stratosphere, the mesosphere, the thermosphere, and the exosphere, which is the outer limit of the atmosphere. The dry atmosphere consists almost entirely of nitrogen (78.1% volume mixing ratio) and oxygen (20.9% volume mixing ratio), together with a number of trace gases, such as argon (0.93 % volume mixing ratio), helium and radiatively active *greenhouse gases (GHGs)* such as *carbon dioxide (CO₂)* (0.04% volume mixing ratio), *methane (CH₄)*, *nitrous oxide (N₂O)* and *ozone (O₃)*. In addition, the atmosphere contains the GHG water vapour (H₂O), whose concentrations are highly variable (0–5% volume mixing ratio) as the sources (*evapotranspiration*) and sinks (precipitation) of water vapour show large spatio-temporal variations, and atmospheric temperature exerts a strong constraint on the amount of water vapour an air parcel can hold. The atmosphere also contains clouds and *aerosols*.

Avoid, Shift, Improve (ASI) Reducing *greenhouse gas* emissions by avoiding the use of an emissions-producing service entirely, shifting to the lowest-emission mode of providing the service, and/or improving the technologies and systems for providing the service in ways that reduce emissions.

Baseline/reference See *Reference period* and *Reference scenario*.

Baseline period See *Reference period*.

Biochar Relatively stable, carbon-rich material produced by heating *biomass* in an oxygen-limited environment. Biochar is distinguished from charcoal by its application: biochar is used as a soil amendment with the intention to improve soil functions and to reduce *greenhouse gas* emissions from *biomass* that would otherwise decompose rapidly (IBI 2018). See also *Anthropogenic removals* and *Carbon dioxide removal (CDR)*.

Biodiversity Biodiversity or biological diversity means the variability among living organisms from all sources including, among other things, terrestrial, marine and other aquatic *ecosystems*, and the ecological complexes of which they are part; this includes diversity within species, between species, and of ecosystems (UN 1992). See also *Bioenergy* and *Biomass*.

Bioenergy Energy derived from any form of *biomass* or its metabolic by-products. See also *Biofuel*.

Bioenergy with carbon dioxide capture and storage (BECCS) *Carbon dioxide capture and storage (CCS)* technology applied to a *bioenergy* facility. Note that, depending on the total emissions of the BECCS supply chain, *carbon dioxide (CO₂)* can be removed from the *atmosphere*. See also *Anthropogenic removals* and *Carbon dioxide removal*.

Biofuel A fuel, generally in liquid form, produced from *biomass*. Biofuels include bioethanol from sugarcane, sugar beet or maize, and biodiesel from canola or soybeans. See also *Bioenergy*.

Biogenic carbon emissions Carbon released as *carbon dioxide* or *methane* from combustion or decomposition of *biomass* or biobased products.

Biomass Organic material excluding the material that is fossilised or embedded in geological formations. Biomass may refer to the mass of organic matter in a specific area (ISO 2014). See also *Bioenergy* and *Biofuel*.

Traditional biomass

The combustion of wood, charcoal, agricultural residues and/or animal dung for cooking or heating in open fires or in inefficient stoves as is common in low-income countries.

Black carbon (BC) A relatively pure form of carbon, also known as soot, arising from the incomplete combustion of *fossil fuels*, *biofuel*, and *biomass*. It only stays in the *atmosphere* for days or weeks. BC is a climate forcing agent with strong warming effect, both in the atmosphere and when deposited on snow or ice. See also *Aerosol*.

Blue carbon Biologically-driven carbon fluxes and storage in marine systems that are amenable to management. Coastal blue carbon focuses on rooted vegetation in the coastal zone, such as tidal marshes, mangroves and seagrasses. These *ecosystems* have high carbon burial rates on a per unit area basis and accumulate carbon in their soils and sediments. They provide many non-climatic benefits and can contribute to *ecosystem-based adaptation*. If degraded or lost, coastal blue carbon ecosystems are likely to release most of their carbon back to the *atmosphere*. There is current debate regarding the application of the blue carbon concept to other coastal and non-coastal processes and ecosystems, including the open ocean. See also *Sequestration*.

Blue infrastructure See *Infrastructure*.

Business as usual (BAU) The term *business as usual* scenario has been used to describe a scenario that assumes no additional policies beyond those currently in place and that patterns of socio-economic development are consistent with recent trends. The term is now used less frequently than in the past. See also *Reference scenario* (under *Scenario*).

Carbon budget Refers to two concepts in the literature: (i) an assessment of carbon cycle *sources* and *sinks* on a global level, through the synthesis of evidence for *fossil fuel* and cement emissions, emissions and removals associated with *land use* and *land-use change*, ocean and natural land sources and sinks of *carbon dioxide (CO₂)*, and the resulting change in atmospheric CO₂ concentration. This is referred to as the global carbon budget; (ii) the maximum amount of cumulative net global *anthropogenic* CO₂ emissions that would result in limiting *global warming* to a given level with a given probability, taking into account the effect of other anthropogenic climate *forcers*. This is referred to as the Total Carbon Budget when expressed starting from the *pre-industrial* period, and as the Remaining Carbon Budget when expressed from a recent specified date.

[Note 1: Net anthropogenic CO₂ emissions are anthropogenic CO₂ emissions minus anthropogenic CO₂ removals. See also *Carbon Dioxide Removal (CDR)*.

Note 2: The maximum amount of cumulative net global anthropogenic CO₂ emissions is reached at the time that annual net anthropogenic CO₂ emissions reach zero.

Note 3: The degree to which anthropogenic climate forcers other than CO₂ affect the Total Carbon Budget and Remaining Carbon Budget depends on human choices about the extent to which these forcers are mitigated and their resulting *climate* effects.

Note 4: The notions of a Total Carbon Budget and Remaining Carbon Budget are also being applied in parts of the scientific literature and by some entities at regional, national, or sub-national level. The distribution of global budgets across individual different entities and emitters depends strongly on considerations of equity and other value judgements.]

Carbon cycle The flow of carbon (in various forms, e.g., as *carbon dioxide (CO₂)*, carbon in *biomass*, and carbon dissolved in the ocean as carbonate and bicarbonate) through the atmosphere, hydrosphere, terrestrial and marine biosphere and lithosphere. In this report, the reference unit for the global carbon cycle is GtCO₂ or GtC (one Gigatonne = 1 Gt = 10¹⁵ grams; 1GtC corresponds to 3.664 GtCO₂).

Carbon dioxide (CO₂) A naturally occurring gas, CO₂ is also a by-product of burning *fossil fuels* (such as oil, gas and coal), of burning *biomass*, of *land-use changes* (LUCs) and of industrial processes (e.g., cement production). It is the principal *anthropogenic* greenhouse gas (GHG) that affects the Earth's radiative balance. It is the reference gas against which other GHGs are measured and therefore has a *global warming potential* (GWP) of 1.

Carbon dioxide capture and storage (CCS) A process in which a relatively pure stream of *carbon dioxide (CO₂)* from industrial and energy-related sources is separated (captured), conditioned, compressed and transported to a storage location for long-term isolation from the *atmosphere*. Sometimes referred to as Carbon Capture and Storage. See also *Anthropogenic removals*, *Bioenergy with carbon dioxide capture and storage (BECCS)*, *Carbon dioxide capture and utilisation (CCU)*, *Carbon dioxide removal (CDR)*, and *Sequestration*.

Carbon dioxide capture and utilisation (CCU) A process in which *carbon dioxide (CO₂)* is captured and the carbon then used in a product. The *climate* effect of CCU depends on the product lifetime, the product it displaces, and the CO₂ source (fossil, *biomass* or *atmosphere*). CCU is sometimes referred to as Carbon Dioxide Capture and Use, or Carbon Capture and Utilisation. See also *Anthropogenic removals*, *Carbon dioxide capture and storage (CCS)*, and *Carbon dioxide removal (CDR)*.

Carbon dioxide removal (CDR) *Anthropogenic* activities removing *carbon dioxide (CO₂)* from the *atmosphere* and durably storing it in geological, terrestrial, or ocean reservoirs, or in products. It includes existing and potential anthropogenic enhancement of biological or geochemical CO₂ *sinks* and *direct air carbon dioxide capture and storage (DACCS)*, but excludes natural CO₂ *uptake* not directly caused by human activities. See also *Anthropogenic removals*, *Afforestation*, *Biochar*, *Bioenergy with carbon dioxide capture and storage (BECCS)*, *Carbon dioxide capture and storage (CCS)*, *Enhanced weathering*, *Ocean alkalinisation/Ocean alkalinity enhancement*, *Reforestation*, and *Soil carbon sequestration (SCS)*.

Carbon footprint Measure of the exclusive total amount of emissions of *carbon dioxide (CO₂)* that is directly and indirectly caused by an activity or is accumulated over the lifecycle stages of a product (Wiedmann and Minx 2008).

Household carbon footprint

The carbon footprint of an individual household, inclusive of the direct and indirect *carbon dioxide (CO₂)* emissions associated with home energy use, transportation, food provision, and consumption of other goods and services associated with household expenditures.

Carbon intensity The amount of emissions of *carbon dioxide (CO₂)* released per unit of another variable such as *gross domestic product (GDP)*, output energy use or transport.

Carbon leakage See *Leakage*.

Carbon neutrality Condition in which *anthropogenic carbon dioxide (CO₂)* emissions associated with a subject are balanced by anthropogenic CO₂ removals. The subject can be an entity such as a country, an organisation, a district or a commodity, or an activity such as a service and an event. Carbon neutrality is often assessed over the lifecycle including indirect ('scope 3') emissions, but can also be limited to the emissions and removals, over a specified period, for which the subject has direct control, as determined by the relevant scheme.

[Note 1: Carbon neutrality and *net-zero CO₂ emissions* are overlapping concepts. The concepts can be applied at global or sub-global scales (e.g., regional, national and sub-national). At a global scale, the terms carbon neutrality and *net-zero CO₂ emissions* are equivalent. At sub-global scales, *net-zero CO₂ emissions* is generally applied to emissions and removals under direct control or territorial responsibility of the reporting entity, while carbon neutrality generally includes emissions and removals within and beyond the direct control or territorial responsibility of the reporting entity. Accounting rules specified by *greenhouse gas (GHG)* programmes or schemes can have a significant influence on the quantification of relevant CO₂ emissions and removals.

Note 2: In some cases, achieving carbon neutrality may rely on the supplementary use of *offsets* to balance emissions that remain after actions by the reporting entity are taken into account.]

See also *Greenhouse gas neutrality*, *Land use*, *land-use change and forestry (LULUCF)* and *Net-zero CO₂ emissions*.

Carbon price The price for avoided or released *carbon dioxide (CO₂)* or CO₂-equivalent emissions. This may refer to the rate of a carbon tax, or the price of emission permits. In many models that are used to assess the economic costs of *mitigation*, carbon prices are used as a proxy to represent the level of effort in mitigation policies.

Carbon sink See *Sink*.

Carbon stock The quantity of carbon in a carbon *pool*.

Choice architecture The presentation of choices to consumers, and the impact that presentation has on consumer decision-making.

Circular economy A system with minimal input and operational losses of materials and energy through extensive reduce, reuse, recycling, and recovery activities. Ten strategies for circularity include: Refuse, Rethink, Reduce, Reuse, Repair, Refurbish, Remanufacture, Repurpose, Recycle, Recover.

Cities Cities are open systems, continually exchanging resources, products and services, waste, people, ideas, and finances with the hinterlands and broader world. Cities are complex, self-organising, adaptive, and constantly evolving. Cities also encompass multiple actors with varying responsibilities, capabilities and priorities, as well as processes that transcend the institutional sector-based approach to city administration. Cities are embedded in broader ecological, economic, technical, institutional, legal, and governance structures that enable or often constrain their systemic function, which cannot be separated from wider power relations. Urban processes of physical,

social, and economic nature are causally interlinked, with interactions and feedbacks that result in both intended and unintended impacts on emissions. See also *City region*, *Peri-urban areas* and *Urban*.

Citizen science A voluntary participation of the public in the collection and/or processing of data as part of a scientific study (Silvertown 2009).

City region The areal extent of an individual city's material associations and economic or political influence. The city region concept accepts that rural livelihoods and land uses can be incorporated within the functional activities of a city. This will include dormitory settlements, sources for critical inputs of water, some food, and waste disposal. See also *Cities*, *Region* and *Urban systems*.

Climate Climate in a narrow sense is usually defined as the average weather, or more rigorously, as the statistical description in terms of the mean and variability of relevant quantities over a period of time ranging from months to thousands or millions of years. The classical period for averaging these variables is 30 years, as defined by the World Meteorological Organization (WMO). The relevant quantities are most often surface variables such as temperature, precipitation and wind. Climate in a wider sense is the state, including a statistical description, of the *climate system*.

Climate change A change in the state of the *climate* that can be identified (e.g., by using statistical tests) by changes in the mean and/or the variability of its properties and that persists for an extended period, typically decades or longer. Climate change may be due to natural internal processes or external forcings such as modulations of the solar cycles, volcanic eruptions and persistent *anthropogenic* changes in the composition of the *atmosphere* or in *land use*. Note that the *United Nations Framework Convention on Climate Change (UNFCCC)*, in its Article 1, defines climate change as: 'a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods'. The UNFCCC thus makes a distinction between climate change attributable to human activities altering the atmospheric composition and *climate variability* attributable to natural causes.

Climate change commitment The unavoidable future *climate change* resulting from inertia in the geophysical and socio-economic systems. Different types of climate change commitment are discussed in the literature. Climate change commitment is usually quantified in terms of the further change in temperature, but it includes other future changes, for example in the hydrological cycle, in *extreme weather events*, in extreme climate events, and in sea level.

Zero emissions commitment

The zero emissions commitment is an estimate of the subsequent *global warming* that would result after *anthropogenic emissions* are set to zero. It is determined by both inertia in physical *climate system* components (ocean, cryosphere, land surface) and *carbon cycle* inertia. In its widest sense it refers to emissions of each climate *forcer* including *greenhouses gases*, *aerosols* and their precursors. The climate response to this can be complex due to the different climate response time scale of each climate forcer. A specific sub-category of zero emissions commitment is the Zero CO₂ Emissions Commitment which refers to the climate system response to CO₂ emissions after setting these to net zero. The CO₂-only definition is of specific use in estimating *remaining carbon budgets*.

Climate extreme (extreme weather or climate event) The occurrence of a value of a weather or *climate* variable above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable. By definition, the characteristics of what is called *extreme weather* may vary from place to place in an absolute sense. When a pattern of extreme weather persists for some time, such as a season, it may be classified as an extreme climate event, especially if it yields an average or total that is itself extreme (e.g., high temperature, *drought*, or heavy rainfall over a season). For simplicity, both extreme weather events and extreme climate events are referred to collectively as 'climate extremes'.

Climate finance There is no agreed definition of climate finance. The term 'climate finance' is applied to the financial resources devoted to addressing climate change by all public and private actors from global to local scales, including international financial flows to developing countries to assist them in addressing climate change. Climate finance aims to reduce net *greenhouse gas* emissions and/or to enhance adaptation and increase resilience to the impacts of current and projected climate change. Finance can come from private and public sources, channelled by various intermediaries, and is delivered by a range of instruments, including grants, concessional and non-concessional debt, and internal budget reallocations.

Climate governance See *Governance*.

Climate justice See *Justice*.

Climate model A qualitative or quantitative representation of the *climate* system based on the physical, chemical and biological properties of its components, their interactions and feedback processes and accounting for some of its known properties. The *climate system* can be represented by models of varying complexity; that is, for any one component or combination of components a spectrum or hierarchy of models can be identified, differing in such aspects as the number of spatial dimensions, the extent to which physical, chemical or biological processes are explicitly represented, or the level at which empirical parametrisations are involved. There is an evolution towards more complex models with interactive chemistry and biology. Climate models are applied as a research tool to study and simulate the climate and for operational purposes, including monthly, seasonal and interannual climate predictions. See also *Simple climate model (SCM)* and *Emulators*.

Climate projection Simulated response of the *climate system* to a *scenario* of future emissions or concentrations of *greenhouse gases (GHGs)* and *aerosols* and changes in *land use*, generally derived using *climate models*. Climate projections are distinguished from climate predictions by their dependence on the emission/concentration/radiative forcing *scenario* used, which is in turn based on assumptions concerning, for example, future socio-economic and technological developments that may or may not be realised.

Climate sensitivity The change in the surface temperature in response to a change in the *atmospheric carbon dioxide (CO₂)* concentration or other *radiative forcing*.

Transient climate response (TCR)

The surface temperature response for the hypothetical scenario in which atmospheric *carbon dioxide (CO₂)* increases at 1% yr⁻¹

from *pre-industrial* to the time of a doubling of atmospheric CO₂ concentration (year 70).

Transient climate response to cumulative CO₂ emissions (TCRE)

The transient surface temperature change per unit cumulative *carbon dioxide (CO₂)* emissions, usually 1000 GtC. TCRE combines both information on the airborne fraction of cumulative CO₂ emissions (the fraction of the total CO₂ emitted that remains in the *atmosphere*, which is determined by *carbon cycle* processes) and on the *transient climate response (TCR)*.

Climate services Climate services involve the provision of climate information in such a way as to assist decision-making. The service includes appropriate engagement from users and providers, is based on scientifically credible information and expertise, has an effective access mechanism, and responds to user needs (Hewitt et al. 2012).

Climate system The global system consisting of five major components: the *atmosphere*, the hydrosphere, the cryosphere, the lithosphere and the biosphere and the interactions between them. The climate system changes in time under the influence of its own internal dynamics and because of external forcings such as volcanic eruptions, solar variations, orbital forcing, and *anthropogenic* forcings such as the changing composition of the atmosphere and *land-use change*.

Climate variability Deviations of climate variables from a given mean state (including the occurrence of extremes, etc.) at all spatial and temporal scales beyond that of individual weather events. Variability may be intrinsic, due to fluctuations of processes internal to the *climate system* (*internal variability*), or extrinsic, due to variations in natural or anthropogenic external forcing (forced variability). See also *Climate change*.

Co-benefits A positive effect that a policy or measure aimed at one objective has on another objective, thereby increasing the total benefit to society or the environment. Co-benefits are also referred to as ancillary benefits. See also *Adverse side-effect* and *Trade-off*.

CO₂ equivalent (CO₂-eq) emission The amount of *carbon dioxide (CO₂)* emission that would have an equivalent effect on a specified key measure of *climate change*, over a specified time horizon, as an emitted amount of another *greenhouse gas (GHG)* or a mixture of other GHGs. For a mix of GHGs, it is obtained by summing the CO₂-equivalent emissions of each gas. There are various ways and time horizons to compute such equivalent emissions (see *greenhouse gas emission metric*). CO₂-equivalent emissions are commonly used to compare emissions of different GHGs, but should not be taken to imply that these emissions have an equivalent effect across all key measures of climate change.

[Note: Under the Paris Rulebook [Decision 18/CMA.1, annex, paragraph 37], parties have agreed to use GWP100 values from the IPCC AR5 or GWP100 values from a subsequent IPCC Assessment Report to report aggregate emissions and removals of GHGs. In addition, parties may use other metrics to report supplemental information on aggregate emissions and removals of GHGs.]

Concentrations scenario See *Scenario*.

Conference of the Parties (COP) The supreme body of UN conventions, such as the *United Nations Framework Convention on*

Climate Change (UNFCCC), comprising parties with a right to vote that have ratified or acceded to the convention.

Confidence The robustness of a finding based on the type, amount, quality and consistency of *evidence* (e.g., mechanistic understanding, theory, data, models, expert judgement) and on the degree of *agreement* across multiple lines of evidence. In this report, confidence is expressed qualitatively (Mastrandrea et al. 2010).

Conservation agriculture A farming system that promotes minimum soil disturbance (e.g., by using no till practices), maintenance of a permanent soil cover, and diversification of plant species. It aims to prevent *land degradation* and regenerate degraded lands by enhancing *biodiversity* and natural biological processes above and below the ground surface, that contribute to increased water and nutrient use efficiency and improved and sustained crop production (FAO 2016).

Consumption-based emissions Emissions released to the atmosphere in order to generate the goods and services consumed by a certain entity (e.g., a person, firm, country, or region). See also *Production-based emissions*.

Coping capacity The ability of people, *institutions*, organisations, and systems, using available skills, values, beliefs, resources, and opportunities, to address, manage, and overcome adverse conditions in the short to medium term (UNISDR 2009; IPCC 2012). See also *Resilience*.

Cost-benefit analysis A type of economic evaluation that compares all monetised negative and positive impacts associated with a given action. Cost-benefit analysis enables comparison of different interventions, investments or strategies, and reveals how a given investment or policy effort pays off for a particular person, company or country, or at a global scale. Cost-benefit analyses representing society's point of view are important for *climate change* decision-making, but there are difficulties in aggregating costs and benefits across different actors and across time scales. See also *Discounting*.

Cost-effectiveness analysis (CEA) A type of economic evaluation that compares the costs of different courses of action reaching the same outcome. In this report, CEA focuses on comparing the costs of *mitigation* strategies designed to meet a prespecified *climate change* mitigation goal (e.g., an emission-reduction target or a temperature stabilisation target).

Cumulative emissions The total amount of emissions released over a specified period of time. See also *Carbon budget* and *Transient climate response to cumulative CO₂ emissions (TCRE)*.

Decarbonisation Human actions to reduce *carbon dioxide* emissions from human activities.

Decent Living Standard A set of minimal material requirements essential for achieving basic human *well-being* including nutrition, shelter, basic living conditions, clothing, healthcare, education, and mobility (Rao and Baer 2012; Rao and Min 2018; O'Neill et al. 2018).

Decoupling Decoupling (in relation to climate change) is where economic growth is no longer strongly associated with another relevant indicator such as *greenhouse gas* emissions. Relative decoupling is where both these indicators grow but the other indicators grow

more slowly than the economy. Absolute decoupling is where there is economic growth but there is a decline in the other indicator.

Deforestation Conversion of *forest* to non-forest.

[Note: For a discussion of the term *forest* and related terms such as *afforestation*, *reforestation* and *deforestation*, see the 2006 IPCC Guidelines for National Greenhouse Gas Inventories and their 2019 Refinement, and information provided by the United Nations Framework Convention on Climate Change (IPCC 2006, 2019; UNFCCC 2021a,b).]

See also *Reducing Emissions from Deforestation and Forest Degradation (REDD+)*.

Deliberative governance See *Governance*.

Demand Disciplinary approaches use the term in different ways. In economics, demand by a consumer is willingness and ability to purchase in a marketplace. However, the motivation for purchase may vary and can include economic utility, welfare, *Decent standard of living (DSL)*, or for the good/services.

Demand- and supply-side measures

Demand-side measures

Policies and programmes for influencing the *demand* for goods and/or services. In the energy sector, demand-side mitigation measures aim at reducing the amount of *greenhouse gas* emissions emitted per unit of energy service used.

Supply-side measures

Policies and programmes for influencing how a certain *demand* for goods and/or services is met. In the energy sector, supply-side mitigation measures aim at reducing the amount of *greenhouse gas* emissions emitted per unit of energy service produced.

Demand-side management See *Demand-side measures*.

Desertification *Land degradation* in arid, semi-arid, and dry sub-humid areas resulting from many factors, including climatic variations and human activities (UNCCD 1994).

Developed/developing countries (Industrialised/developed/developing countries) There is a diversity of approaches for categorising countries on the basis of their level of development, and for defining terms such as 'industrialised', 'developed', or 'developing'. Several categorisations are used in this report: (i) In the United Nations (UN) system, there is no established convention for the designation of developed and developing countries or areas. (ii) The UN Statistics Division specifies developed and developing regions based on common practice. In addition, specific countries are designated as least developed countries, landlocked developing countries, *Small Island Developing States (SIDS)*, and transition economies. Many countries appear in more than one of these categories. (iii) The World Bank uses income as the main criterion for classifying countries as low, lower middle, upper middle, and high income. (iv) The UN Development Programme (UNDP) aggregates indicators for life expectancy, educational attainment, and income into a single composite Human Development Index (HDI) to classify countries as low, medium, high, or very high human development.

Development pathway See *Pathways*.

Diet The kinds of food that follow a particular pattern that a person or community eats (FAO and Alliance of Bioversity International and CIAT, 2021).

Direct air capture (DAC) Chemical process by which a pure *carbon dioxide* (CO_2) stream is produced by capturing CO_2 from the ambient air. See also *Anthropogenic removals*, *Carbon dioxide removal (CDR)* and *Direct air carbon dioxide capture and storage (DACCS)*.

Direct air carbon dioxide capture and storage (DACCS) Chemical process by which *carbon dioxide* (CO_2) is captured directly from the ambient air, with subsequent storage. Also known as direct air capture and storage (DAC). See also *Anthropogenic removals*, *Carbon dioxide removal (CDR)* and *Direct air capture (DAC)*.

Direct and indirect services Direct Services: Services (e.g., passenger mobility) required by end-users (consumers). Indirect services: Services required (e.g., goods transport, manufacturing) for provisioning systems of direct services.

Direct emissions Emissions that physically arise from activities within well-defined boundaries of, for instance, a *region*, an economic sector, a company, or a process. See also *Indirect emissions*.

Disaster A 'serious disruption of the functioning of a community or a society at any scale due to hazardous events interacting with conditions of exposure, vulnerability and capacity, leading to one or more of the following: human, material, economic and environmental losses and impacts' (UNGA 2016). See also *Exposure*, *Hazard*, *Risk* and *Vulnerability*.

Disaster risk management (DRM) Processes for designing, implementing, and evaluating strategies, policies, and measures to improve the understanding of current and future disaster *risk*, foster *disaster* risk reduction and transfer, and promote continuous improvement in disaster preparedness, prevention and protection, response, and recovery practices, with the explicit purpose of increasing human security, *well-being*, quality of life, and *sustainable development (SD)*.

Discount rate See *Discounting*.

Discounting A mathematical operation that aims to make monetary (or other) amounts received or expended at different times (years) comparable across time. If the discount rate is positive, future values are given less weight than those today. The choice of discount rate(s) is debated as it is a judgement based on hidden and/or explicit values.

Disruptive innovation Demand-led technological change that leads to significant system change and is characterised by strong exponential growth.

Distributive equity See *Equity*.

Drought An exceptional period of water shortage for existing *ecosystems* and the human population (due to low rainfall, high temperature, and/or wind).

Ecosystem A functional unit consisting of living organisms, their non-living environment and the interactions within and between them. The components included in a given ecosystem and its spatial boundaries depend on the purpose for which the ecosystem is defined: in some cases they are relatively sharp, while in others they are diffuse. Ecosystem boundaries can change over time.

Ecosystems are nested within other ecosystems and their scale can range from very small to the entire biosphere. In the current era, most ecosystems either contain people as key organisms, or are influenced by the effects of human activities in their environment. See also *Ecosystem services*.

Ecosystem services Ecological processes or functions having monetary or non-monetary value to individuals or society at large. These are frequently classified as: (i) supporting services such as productivity or biodiversity maintenance; (ii) provisioning services such as food or fibre; (iii) regulating services such as climate regulation or carbon *sequestration*; and (iv) cultural services such as tourism or spiritual and aesthetic appreciation. See also *Ecosystem* and *Nature's Contribution to People*.

Ecosystem-based adaptation (EBA) The use of *ecosystem* management activities to increase the *resilience* and reduce the *vulnerability* of people and *ecosystems* to *climate change* (Campbell et al. 2009).

Embodied (embedded) [emissions, water, land] The total emissions [water use, *land use*] generated [used] in the production of goods and services regardless of the location and timing of those emissions [water use, land use] in the production process. This includes emissions [water use, land use] within the country used to produce goods or services for the country's own use, but also includes the emissions [water use, land use] related to the production of such goods or services in other countries that are then consumed in another country through imports. Such emissions [water, land] are termed 'embodied' or 'embedded' emissions, or, in some cases, (particularly with water) as 'virtual water use' (Davis and Caldeira 2010; Allan 2005; MacDonald et al. 2015).

Emission and Socio-economic Scenario Ensemble A set of modelled emission and socio-economic *scenarios* collected in a database. The scenarios can come from a single multi-model study with systematic variation of harmonised scenario designs (structured ensemble) or from multiple studies in the literature (unstructured ensemble). Depending on the scope of the ensemble, variation of the results across the scenarios in the ensemble give an indication of the spread of results in the literature (unstructured ensemble), or an estimate of uncertainties due to different modelling structures and methodologies (structured ensemble).

Emission factor/Emissions intensity A coefficient that quantifies the emissions or removals of a gas per unit activity. Emission factors are often based on a sample of measurement data, averaged to develop a representative rate of emission for a given activity level under a given set of operating conditions.

Emission pathways See *Pathways*.

Emission trajectories A projected development in time of the emission of a *greenhouse gas (GHG)* or group of GHGs, *aerosols*, and GHG *precursors*. See also *Pathways*.

Emissions See *Anthropogenic emissions*, *Direct emissions*, *Cumulative emissions*, *Indirect emissions*, *Consumption-based emissions*, *Production-based emissions* and *Embodied (embedded) [emissions, water, land]*.

Emissions scenario See *Scenario*.

Emulation Reproducing the behaviour of complex, process-based models – namely, Earth System Models (ESMs) – via simpler approaches, using either *emulators* or *simple climate models (SCMs)*. The computational efficiency of emulating approaches opens new analytical possibilities, given that ESMs take a lot of computational resources for each simulation.

Emulators A broad class of heavily parametrised models ('simple climate models'), statistical methods like neural networks, genetic algorithms or other artificial intelligence approaches, designed to reproduce the responses of more complex, process-based Earth System Models (ESMs). The main application of emulators is to extrapolate insights from ESMs and observational constraints to a larger set of emission scenarios. See also *Emulation* and *Simple climate models (SCMs)*.

Enabling conditions (for adaptation and mitigation options) Conditions that enhance the *feasibility* of *adaptation* and *mitigation* options. Enabling conditions include finance, technological innovation, strengthening policy instruments, *institutional capacity*, *multi-level governance*, and changes in *human behaviour* and lifestyles.

Energy access Access to clean, reliable and affordable energy services for cooking and heating, lighting, communications, and productive uses (with special reference to *Sustainable Development Goal 7*) (AGECC 2010). See also *Traditional biomass*.

Energy efficiency The ratio of output or useful energy or energy services or other useful physical outputs obtained from a system, conversion process, transmission or storage activity to the input of energy (measured as kWh kWh⁻¹, tonnes kWh⁻¹ or any other physical measure of useful output like tonne-km transported). Energy efficiency is often described by energy intensity.

Energy poverty The absence of sufficient choice in accessing adequate, affordable, reliable, high quality, safe and environmentally benign energy services to support economic and human development (Reddy 2000). See also *Fuel poverty*.

Energy security The goal of a given country, or the global community as a whole, to maintain an adequate, stable and predictable energy supply. Measures encompass safeguarding the sufficiency of energy resources to meet national energy demand at competitive and stable prices and the resilience of the energy supply; enabling development and deployment of technologies; building sufficient infrastructure to generate, store and transmit energy supplies and ensuring enforceable contracts of delivery.

Energy services A benefit or amenity (e.g., mobility, communication, thermal comfort) received as a result of energy or other resources use.

Enhanced weathering A proposed method to increase the natural rate of removal of *carbon dioxide (CO₂)* from the *atmosphere* using silicate and carbonate rocks. The active surface area of these minerals is increased by grinding, before they are actively added to soil, beaches or the open ocean. See also *Anthropogenic removals* and *Carbon dioxide removal (CDR)*.

Ensemble A collection of comparable datasets that reflect variations within the bounds of one or more sources of *uncertainty*, and that when averaged can provide a more robust estimate of underlying behaviour. Ensemble techniques are used by the

observational, reanalysis and modelling communities. See also *Emission and Socio-economic Scenario Ensemble* and *Integrated Assessment Scenario Ensemble*.

Enteric fermentation A natural part of the digestion process in ruminant animal species (domesticated and wild), such as cattle, buffalo, sheep, goats, antelope, etc. Microorganisms (bacteria, archaea, fungi, protozoa and viruses) present in the fore-stomach (reticulorumen or rumen) breakdown plant *biomass* to produce substrates that can be used by the animal for energy and growth with methane produced as a by-product. Fermentation end-products such as hydrogen, *carbon dioxide*, formate and methyl-containing compounds are important substrates for the production of methane by the rumen's methane-forming archaea (known as methanogens).

Equality A principle that ascribes equal worth to all human beings, including equal opportunities, rights, and obligations, irrespective of origins.

Inequality

Uneven opportunities and social positions, and processes of discrimination within a group or society, based on gender, class, ethnicity, age, and (dis)ability, often produced by uneven development. Income inequality refers to gaps between highest and lowest income earners within a country and between countries.

See also *Equity* and *Fairness*.

Equity The principle of being fair and impartial, and a basis for understanding how the *impacts* and responses to *climate change*, including costs and benefits, are distributed in and by society in more or less equal ways. Often aligned with ideas of *equality*, *fairness* and *justice* and applied with respect to equity in the responsibility for, and distribution of, *climate* impacts and policies across society, generations, and gender, and in the sense of who participates and controls the processes of decision-making.

Distributive equity

Equity in the consequences, outcomes, costs and benefits of actions or policies. In the case of *climate change* or climate policies for different people, places and countries, including equity aspects of sharing burdens and benefits for mitigation and adaptation.

Gender equity

Equity between women and men with regard to their rights, resources and opportunities. In the case of climate change, gender equity recognises that women are often more vulnerable to the impacts of climate change and may be disadvantaged in the process and outcomes of climate policy.

Inter-generational equity

Equity between generations. In the context of climate change, inter-generational equity acknowledges that the effects of past and present emissions, vulnerabilities and policies impose costs and benefits for people in the future and of different age groups.

Evidence Data and information used in the scientific process to establish findings. In this report, the degree of evidence reflects the amount, quality and consistency of scientific/technical information on which the Lead Authors are basing their findings. See also *Agreement*, *Confidence*, *Likelihood*, and *Uncertainty*.

Exergy Capacity of energy flows to perform useful work. Exergy is a quality (versatility) indicator of energy flows which ranges from low (e.g., low-temperature heat, biomass) to high (e.g., electricity). Exergy efficiency describes how much useful work can be performed by a particular energy flow in relation to the thermodynamic maximum possible. It can be determined for all energy flows and energy conversion steps, also including alternative service delivery systems (Grubler et al. 2012).

Exposure The presence of people; *livelihoods*; species or *ecosystems*; environmental functions, services, and resources; infrastructure; or economic, social, or cultural assets in places and settings that could be adversely affected.

Extreme weather event An event that is rare at a particular place and time of year. Definitions of 'rare' vary, but an extreme weather event would normally be as rare as, or rarer than, the 10th or 90th percentile of a probability density function estimated from observations. By definition, the characteristics of what is called extreme weather may vary from place to place in an absolute sense. See also *Climate extreme (extreme weather or climate event)*.

Fairness Impartial and just treatment without favouritism or discrimination in which each person is considered of equal worth with equal opportunity. See also *Equality* and *Equity*.

Feasibility In this report, feasibility refers to the potential for a mitigation or adaptation option to be implemented. Factors influencing feasibility are context-dependent, temporally dynamic, and may vary between different groups and actors. Feasibility depends on geophysical, environmental-ecological, technological, economic, socio-cultural and institutional factors that enable or constrain the implementation of an option. The feasibility of options may change when different options are combined, and increase when enabling conditions are strengthened. See also *Enabling conditions (for adaptation and mitigation options)*.

Final energy The energy delivered to final users (firms, individuals, *institutions*), where it becomes usable energy in supplying energy services (e.g., light, heat, mobility). See also *Primary energy*.

Flexibility (demand and supply) Adjustment of energy load characteristics by technical and/or non-technical change to balance energy demand and supply.

Flexible governance See *Governance*.

Flood The overflowing of the normal confines of a stream or other water body, or the accumulation of water over areas that are not normally submerged. Floods can be caused by unusually heavy rain, for example, during storms and cyclones. Floods include river (fluvial) floods, flash floods, *urban* floods, rain (pluvial) floods, sewer floods, coastal floods, and glacial lake outburst floods (GLOFs).

Food loss and waste 'The decrease in quantity or quality of food'. Food waste is part of food loss and refers to discarding or alternative (non-food) use of food that is safe and nutritious for human consumption along the entire food supply chain, from primary production to end household consumer level. Food waste is recognised as a distinct part of food loss because the drivers that generate it and the solutions to it are different from those of food losses (FAO 2015).

Food security A situation that exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life. The four pillars of food security are: availability; access; utilisation; and stability. The nutritional dimension is integral to the concept of food security (FAO 2009, 2018).

Access

Economic and/or physical access to food. Economic access is determined by disposable income, food prices and the provision of and access to social support. Physical access is determined by the availability and quality of land and other infrastructure, property rights or the functioning of markets.

Availability

Physical availability of food. Food availability addresses the supply side of food security and is determined by the levels of food production, stocks and net trade.

Stability

The stability of the other three dimensions over time. Even if individuals' food intake is adequate today, they are still considered food-insecure if periodically they have inadequate access to food, risking deterioration of their nutrition status. Adverse weather conditions, political instability or economic factors (unemployment, rising food prices) may have an impact on individuals' food security status.

Utilisation

The way in which the body uses the various nutrients in food. Individuals achieve sufficient energy and nutrient intake through good care and feeding practices, food preparation, diet diversity and intra-household distribution of food. Combined with biological utilisation of the food consumed, energy and nutrient intake determine the nutrition status of individuals.

Food system All the elements (environment, people, inputs, processes, *infrastructures*, *institutions*, etc.) and activities that relate to the production, processing, distribution, preparation and consumption of food, and the output of these activities, including socio-economic and environmental outcomes (HLPE 2017).

[Note: Whilst there is a global food system (encompassing the totality of global production and consumption), each location's food system is unique, being defined by that place's mix of food produced locally, nationally, regionally or globally.]

Forest A vegetation type dominated by trees. Many definitions of the term forest are in use throughout the world, reflecting wide differences in biogeophysical conditions, social structure and economics.

[Note: For a discussion of the term forest in the context of National GHG inventories, see the 2006 IPCC Guidelines for National GHG Inventories and their 2019 Refinement, and information provided by the United Nations Framework Convention on Climate Change (IPCC 2006, 2019; UNFCCC 2021a,b).]

Fossil fuels Carbon-based fuels from fossil hydrocarbon deposits, including coal, oil, and natural gas.

Fuel poverty A condition in which a household is unable to guarantee a certain level of consumption of domestic energy services

(especially heating) or suffers disproportionate expenditure burdens to meet these needs. See also [Energy poverty](#).

Fugitive emissions (oil and natural gas systems) The release of [greenhouse gases](#) that occur during the exploration, processing and delivery of [fossil fuels](#) to the point of final use. This excludes [greenhouse gas emissions](#) from fuel combustion for the production of useful heat or power. It encompasses venting, flaring, and leaks.

Gender equity See [Equity](#).

Geothermal energy Accessible thermal energy stored in the Earth's interior, in both rock and trapped steam or liquid water (hydrothermal resources), which may be used to generate electric energy in a thermal power plant, or to supply heat to any process requiring it. The main sources of geothermal energy are the residual energy available from planet formation and the energy continuously generated from radionuclide decay. See also [Renewable energy](#).

Gini coefficient A statistical measure of dispersion in a distribution and degree of mathematical measure of [inequality](#). For example, it can be used for measuring inequality in income, wealth, carbon emissions, and access to well-being defining services. The dimensionless GINI coefficient ranges between 0 (absolute [equality](#)) and 1 (absolute inequality).

Global carbon budget See [Carbon budget](#).

Global mean surface air temperature (GSAT) Global average of near-surface air temperatures over land, oceans and sea ice. Changes in GSAT are often used as a measure of global temperature change in [climate models](#). See also [Global mean surface temperature \(GMST\)](#).

Global mean surface temperature (GMST) Estimated global average of near-surface air temperatures over land and sea ice, and [sea surface temperature \(SST\)](#) over ice-free ocean regions, with changes normally expressed as departures from a value over a specified [reference period](#). See also [Global mean surface air temperature \(GSAT\)](#).

Global warming Global warming refers to the increase in [global surface temperature](#) relative to a baseline [reference period](#), averaging over a period sufficient to remove interannual variations (e.g., 20 or 30 years). A common choice for the baseline is 1850–1900 (the earliest period of reliable observations with sufficient geographic coverage), with more modern baselines used depending upon the application. See also [Climate change](#) and [Climate variability](#).

Global warming potential (GWP) An index measuring the [radiative forcing](#) following an emission of a unit mass of a given substance, accumulated over a chosen time horizon, relative to that of the reference substance, [carbon dioxide \(CO₂\)](#). The GWP thus represents the combined effect of the differing times these substances remain in the atmosphere, and their effectiveness in causing radiative forcing. See also [Greenhouse gas emission metric](#).

Governance The structures, processes, and actions through which private and public actors interact to address societal goals. This includes formal and informal [institutions](#) and the associated norms, rules, laws and procedures for deciding, managing, implementing and monitoring policies and measures at any geographic or political scale, from global to local.

Adaptive governance

Adjusting to changing conditions, such as climate change, through governance interactions that seek to maintain a desired state in a social-ecological system.

Climate governance

The structures, processes, and actions through which private and public actors seek to mitigate and adapt to climate change.

Deliberative governance

Deliberative governance involves decision-making through inclusive public conversation which allows opportunity for developing policy options through public discussion rather than collating individual preferences through voting or referenda (although the latter governance mechanisms can also be preceded and legitimated by public deliberation processes).

Flexible governance

Strategies of governance at various levels, which prioritise the use of social learning and rapid feedback mechanisms in planning and policymaking, often through incremental, experimental and iterative management processes.

Multi-level governance

The dispersion of governance across multiple levels of jurisdiction and decision-making, including, global, regional, national and local, as well as trans-regional and trans-national levels.

Participatory governance

A governance system that enables direct public engagement in decision-making using a variety of techniques, for example, referenda, community deliberation, citizen juries or participatory budgeting. The approach can be applied in formal and informal institutional contexts from national to local, but is usually associated with devolved decision-making (Fung and Wright 2003; Sarmiento and Tilly 2018).

Governance capacity The ability of governance [institutions](#), leaders, and non-state and civil society to plan, coordinate, fund, implement, evaluate and adjust policies and measures over the short, medium and long term, adjusting for uncertainty, rapid change and wide-ranging impacts and multiple actors and demands. See also [Governance](#).

Grazing land The sum of rangelands and pastures not considered as cropland, and subject to livestock grazing or hay production. It includes a wide range of [ecosystems](#), for example, systems with vegetation that fall below the threshold used in the [forest](#) land category, silvo-pastoral systems, as well as natural, managed grasslands and semi-deserts.

Green Climate Fund (GCF) The GCF was established by the 16th Session of the [Conference of the Parties \(COP\)](#) in 2010 as an operating entity of the financial mechanism of the [United Nations Framework Convention on Climate Change \(UNFCCC\)](#), in accordance with Article 11 of the Convention, to support projects, programmes and policies and other activities in developing country Parties. The Fund is governed by a Board and will receive guidance of the COP. See also [Climate finance](#).

Green infrastructure See *Infrastructure*.

Greenhouse gas emission metric A simplified relationship used to quantify the effect of emitting a unit mass of a given *greenhouse gas (GHG)* on a specified key measure of *climate change*. A relative GHG emission metric expresses the effect from one gas relative to the effect of emitting a unit mass of a reference GHG on the same measure of climate change. There are multiple emission metrics, and the most appropriate metric depends on the application. GHG emission metrics may differ with respect to: (i) the key measure of climate change they consider; (ii) whether they consider climate outcomes for a specified point in time or integrated over a specified time horizon; (iii) the time horizon over which the metric is applied; (iv) whether they apply to a single emission pulse, emissions sustained over a period of time, or a combination of both; and (v) whether they consider the climate effect from an emission compared to the absence of that emission or compared to a reference emissions level or climate state.

[Note: Most relative GHG emission metrics (such as the *global warming potential (GWP)*, global temperature change potential (GTP), global damage potential, and GWP*), use carbon dioxide (CO_2) as the reference gas. Emissions of non- CO_2 gases, when expressed using such metrics, are often referred to as 'carbon dioxide equivalent' emissions. A metric that establishes equivalence regarding one key measure of the *climate system* response to emissions does not imply equivalence regarding other key measures. The choice of a metric, including its time horizon, should reflect the policy objectives for which the metric is applied.]

Greenhouse gas neutrality Condition in which metric-weighted anthropogenic *greenhouse gas (GHG)* emissions associated with a subject are balanced by metric-weighted *anthropogenic* GHG removals. The subject can be an entity such as a country, an organisation, a district or a commodity, or an activity such as a service and an event. GHG neutrality is often assessed over the lifecycle, including indirect ('scope 3') emissions, but can also be limited to the emissions and removals, over a specified period, for which the subject has direct control, as determined by the relevant scheme. The quantification of GHG emissions and removals depends on the GHG emission metric chosen to compare emissions and removals of different gases, as well as the time horizon chosen for that metric.

[Note 1: Greenhouse gas neutrality and net-zero greenhouse gas emissions are overlapping concepts. The concepts can be applied at global or sub-global scales (e.g., regional, national and sub-national). At a global scale, the terms greenhouse gas neutrality and net-zero greenhouse gas emissions are equivalent. At sub-global scales, net-zero GHG emissions is generally applied to emissions and removals under direct control or territorial responsibility of the reporting entity, while GHG neutrality generally includes emissions and removals within and beyond the direct control or territorial responsibility of the reporting entity. Accounting rules specified by GHG programmes or schemes can have a significant influence on the quantification of relevant emissions and removals.]

Note 2: Under the Paris Rulebook (Decision 18/CMA.1, annex, paragraph 37), parties have agreed to use GWP100 values from the IPCC AR5 or GWP100 values from a subsequent IPCC Assessment Report to report aggregate emissions and removals of GHGs. In addition, parties may use other metrics to report supplemental information on aggregate emissions and removals of GHGs.

Note 3: In some cases, achieving greenhouse gas neutrality may rely on the supplementary use of *offsets* to balance emissions that remain after actions by the reporting entity are taken into account.]

See also *Carbon neutrality*, *Greenhouse gas emission metric*, *Land use*, *Land-use change and forestry (LULUCF)* and *Net-zero greenhouse gas emissions*.

Greenhouse gases (GHGs) Gaseous constituents of the *atmosphere*, both natural and *anthropogenic*, that absorb and emit radiation at specific wavelengths within the spectrum of radiation emitted by the Earth's surface, by the atmosphere itself, and by clouds. This property causes the *greenhouse effect*. Water vapour (H_2O), *carbon dioxide* (CO_2), *nitrous oxide* (N_2O), *methane* (CH_4) and *ozone* (O_3) are the primary GHGs in the Earth's atmosphere. Human-made GHGs include sulphur hexafluoride (SF_6), hydrofluorocarbons (HFCs), chlorofluorocarbons (CFCs) and perfluorocarbons (PFCs); several of these are also O_3 -depleting (and are regulated under the Montreal Protocol).

Grey infrastructure See *Infrastructure*.

Gross domestic product (GDP) The sum of gross value added, at purchasers' prices, by all resident and non-resident producers in the economy, plus any taxes and minus any subsidies not included in the value of the products in a country or a geographic region for a given period, normally one year. GDP is calculated without deducting for depreciation of fabricated assets or depletion and degradation of natural resources.

Halocarbons A collective term for the group of partially halogenated organic species, which includes the chlorofluorocarbons (CFCs), hydrochlorofluorocarbons (HCFCs), hydrofluorocarbons (HFCs), halons, methyl chloride and methyl bromide. Many of the halocarbons have large *global warming potentials*. The chlorine and bromine-containing halocarbons are also involved in the depletion of the ozone layer.

Human behaviour The responses of persons or groups to a particular situation, here likely to relate to *climate change*. Human behaviour covers the range of actions by individuals, communities, *organisations*, governments and at the international level.

Human rights Rights that are inherent to all human beings, universal, inalienable, and indivisible, typically expressed and guaranteed by law. They include the right to life, economic, social, and cultural rights, and the right to development and self-determination (OHCHR 2018).

Human security A condition that is met when the vital core of human lives is protected, and when people have the freedom and capacity to live with dignity. In the context of *climate change*, the vital core of human lives includes the universal and culturally specific, material and non-material elements necessary for people to act on behalf of their interests and to live with dignity.

Human system Any system in which human organisations and *institutions* play a major role. Often, but not always, the term is synonymous with society or social system. Systems such as agricultural systems, urban systems, political systems, technological systems and economic systems are all human systems in the sense applied in this report.

Hydropower Power harnessed from the flow of water. See also [Renewable energy](#).

Impacts The consequences of realised [risks](#) on natural and [human systems](#), where risks result from the interactions of climate-related [hazards](#) (including [extreme weather/climate events](#)), [exposure](#), and [vulnerability](#). Impacts generally refer to effects on lives, [livelihoods](#), health and [well-being](#), [ecosystems](#) and species, economic, social and cultural assets, services (including [ecosystem services](#)), and [infrastructure](#). Impacts may be referred to as consequences or outcomes, and can be adverse or beneficial. See also [Adaptation](#), [Loss and Damage](#), and [losses and damages](#).

Indigenous knowledge The understandings, skills and philosophies developed by societies with long histories of interaction with their natural surroundings. For many indigenous peoples, indigenous knowledge informs decision-making about fundamental aspects of life, from day-to-day activities to longer-term actions. This knowledge is integral to cultural complexes, which also encompass language, systems of classification, resource use practices, social interactions, values, ritual and spirituality. These distinctive ways of knowing are important facets of the world's cultural diversity (UNESCO 2018). See also [Local knowledge](#).

Indirect emissions Emissions that are a consequence of the activities within well-defined boundaries of, for instance, a [region](#), an economic sector, a company or process, but which occur outside the specified boundaries. For example, emissions are described as indirect if they relate to the use of heat but physically arise outside the boundaries of the heat user, or to electricity production but physically arise outside of the boundaries of the power supply sector. See also [Direct emissions](#).

Indirect land-use change (iLUC) See [Land-use change \(LUC\)](#).

Industrial revolution A period of rapid industrial growth with far-reaching social and economic consequences, beginning in Britain during the second half of the 18th century and spreading to Europe and later to other countries including the United States. The invention of the steam engine was an important trigger of this development. The industrial revolution marks the beginning of a strong increase in the use of [fossil fuels](#), initially coal, and hence emission of [carbon dioxide \(CO₂\)](#).

Inequality See [Equality](#).

Infrastructure The designed and built set of physical systems and corresponding [institutional](#) arrangements that mediate between people, their communities, and the broader environment to provide services that support economic growth, health, quality of life, and safety (Chester 2019; Dawson et al. 2018).

Blue infrastructure

Blue infrastructure includes bodies of water, watercourses, ponds, lakes and storm drainage, that provide ecological and hydrological functions including evaporation, transpiration, drainage, infiltration, and temporary storage of runoff and discharge.

Green infrastructure

The strategically planned interconnected set of natural and constructed ecological systems, green spaces and other landscape features that can provide functions and services including air

and water purification, temperature management, floodwater management and coastal defence often with co-benefits for people and biodiversity. Green infrastructure includes planted and remnant native vegetation, soils, wetlands, parks and green open spaces, as well as building and street-level design interventions that incorporate vegetation (Bobbins and Culwick 2016).

Grey infrastructure

Engineered physical components and networks of pipes, wires, roads, tracks that underpin energy, transport, communications (including digital), built form, water and sanitation and solid waste management systems.

Social infrastructure

The social, cultural, and financial activities and institutions as well as associated property, buildings and artefacts and policy domains such as social protection, health and education that support well-being and public life (Latham and Layton 2019; Frolova et al. 2016).

Institutional capacity Building and strengthening individual organisations and providing technical and management training to support integrated planning and decision-making processes between organisations and people, as well as empowerment, social capital, and an enabling environment, including the culture, values and power relations (Willems and Baumert 2003). See also [Governance](#) and [Institutions](#).

Institutions Rules, norms and conventions that guide, constrain or enable human behaviours and practices. Institutions can be formally established, for instance through laws and regulations, or informally established, for instance by traditions or customs. Institutions may spur, hinder, strengthen, weaken or distort the emergence, adoption and implementation of climate action and climate governance.

[Note: Institutions can also refer to a large organisation.]

See also [Institutional capacity](#).

Integrated assessment A method of analysis that combines results and models from the physical, biological, economic and social sciences and the interactions among these components in a consistent framework to evaluate the status and the consequences of environmental change and the policy responses to it. See also [Integrated assessment model \(IAM\)](#).

Integrated assessment model (IAM) Models that integrate knowledge from two or more domains into a single framework. They are one of the main tools for undertaking integrated assessments. One class of IAM used with respect to climate change [mitigation](#) may include representations of: multiple sectors of the economy, such as energy, [land use](#) and [land-use change](#); interactions between sectors; the economy as a whole; associated [greenhouse gas \(GHG\)](#) emissions and [sinks](#); and reduced representations of the [climate system](#). This class of model is used to assess linkages between economic, social and technological development and the evolution of the climate system. Another class of IAM additionally includes representations of the costs associated with climate change [impacts](#), but includes less detailed representations of economic systems. These can be used to assess impacts and mitigation in a cost–benefit framework and have been used to estimate the [social cost of carbon](#). See also [Integrated Assessment Scenario Ensemble](#).

Integrated Assessment Scenario Ensemble A set of modelled scenarios from an intercomparison of *integrated assessment models (IAMs)* based on a systematic variation of harmonised scenario designs.

Inter-generational equity See *Equity*.

Internet of Things (IoT) The network of computing devices embedded in everyday objects such as cars, phones and computers, connected via the internet, enabling them to send and receive data.

Irreversibility A perturbed state of a dynamical system is defined as irreversible on a given time scale if the recovery from this state due to natural processes takes substantially longer than the time scale of interest. See also *Tipping point*.

Just transitions A set of principles, processes and practices that aim to ensure that no people, workers, places, sectors, countries or regions are left behind in the transition from a high-carbon to a low-carbon economy. It stresses the need for targeted and proactive measures from governments, agencies, and authorities to ensure that any negative social, environmental or economic impacts of economy-wide transitions are minimised, whilst benefits are maximised for those disproportionately affected. Key principles of just transitions include: respect and dignity for vulnerable groups; fairness in energy access and use, social dialogue and democratic consultation with relevant stakeholders; the creation of decent jobs; social protection; and rights at work. Just transitions could include fairness in energy, land use and climate planning and decision-making processes; economic diversification based on low-carbon investments; realistic training/retraining programmes that lead to decent work; gender-specific policies that promote equitable outcomes; the fostering of international cooperation and coordinated multilateral actions; and the eradication of poverty. Lastly, just transitions may embody the redressing of past harms and perceived injustices (ILO 2015; UNFCCC 2016).

Justice Justice is concerned with ensuring that people get what is due to them, setting out the moral or legal principles of *fairness* and *equity* in the way people are treated, often based on the ethics and values of society.

Climate justice

Justice that links development and human rights to achieve a human-centred approach to addressing *climate change*, safeguarding the rights of the most vulnerable people and sharing the burdens and benefits of climate change and its impacts equitably and fairly (MRFCJ 2018).

Kaya identity In this identity, global emissions are equal to the population size, multiplied by per capita output (gross world product), multiplied by the energy intensity of production, multiplied by the carbon intensity of energy.

Land The terrestrial portion of the biosphere that comprises the natural resources (soil, near-surface air, vegetation and other biota, and water), the ecological processes, topography, and *human settlements* and infrastructure that operate within that system (FAO 2007; UNCCD 1994).

Land cover The biophysical coverage of *land* (e.g., bare soil, rocks, forests, buildings and roads or lakes). Land cover is often categorised

in broad land-cover classes (e.g., deciduous forest, coniferous forest, mixed forest, grassland, bare ground).

[Note: In some literature, land cover and land use are used interchangeably, but the two represent distinct classification systems. For example, the land cover class woodland can be under various land uses such as livestock grazing, recreation, conservation, or wood harvest.]

Land cover change Change from one *land cover* class to another, due to change in *land use* or change in natural conditions (Pongratz et al. 2018).

Land degradation A negative trend in land condition, caused by direct or indirect human-induced processes including *anthropogenic* climate change, expressed as long-term reduction or loss of at least one of the following: biological productivity, ecological integrity or value to humans.

[Note: This definition applies to *forest* and non-forest land. Changes in land condition resulting solely from natural processes (such as volcanic eruptions) are not considered to be land degradation. Reduction of biological productivity or ecological integrity or value to humans can constitute degradation, but any one of these changes need not necessarily be considered degradation.]

See also *Desertification*.

Land degradation neutrality A state whereby the amount and quality of land resources necessary to support *ecosystem* functions and services and enhance *food security* remain stable or increase within specified temporal and spatial scales and ecosystems (UNCCD 2020).

Land management Sum of land-use practices (e.g., sowing, fertilising, weeding, harvesting, thinning, clear-cutting) that take place within broader *land-use* categories (Pongratz et al. 2018).

Land management change

A change in land management that occurs within a *land-use* category.

Land potential The inherent, long-term potential of the *land* to sustainably generate *ecosystem services*, which reflects the capacity and *resilience* of the land-based natural capital, in the face of ongoing environmental change (UNEP 2016).

Land rehabilitation Direct or indirect actions undertaken with the aim of reinstating a level of *ecosystem* functionality, where the goal is provision of goods and services rather than ecological restoration (McDonald et al. 2016).

Land restoration The process of assisting the recovery of *land* from a degraded state (IPBES 2018; McDonald et al. 2016).

Land use The total of arrangements, activities and inputs applied to a parcel of *land*. The term land use is also used in the sense of the social and economic purposes for which land is managed (e.g., grazing, timber extraction, conservation and city dwelling). In national *greenhouse gas (GHG)* inventories, land use is classified according to the IPCC land-use categories of forest land, cropland, grassland, wetlands, settlements, other lands (see the 2006 IPCC Guidelines for National GHG Inventories and their 2019 Refinement for details (IPCC 2006, 2019)).

Land use, land-use change and forestry (LULUCF) In the context of national greenhouse gas (GHG) inventories under

the *United Nations Framework Convention on Climate Change* (UNFCCC 2019), LULUCF is a GHG inventory sector that covers *anthropogenic* emissions and removals of GHG in managed lands, excluding non-CO₂ agricultural emissions. Following the 2006 IPCC Guidelines for National GHG Inventories and their 2019 Refinement, 'anthropogenic' land-related GHG fluxes are defined as all those occurring on 'managed land', that is, 'where human interventions and practices have been applied to perform production, ecological or social functions'. Since managed land may include *carbon dioxide* (CO₂), removals not considered as 'anthropogenic' in some of the scientific literature assessed in this report (e.g., removals associated with CO₂ fertilisation and N deposition), the land-related net GHG emission estimates from global models included in this report are not necessarily directly comparable with LULUCF estimates in National GHG Inventories (IPCC 2006, 2019).

Land-use change (LUC) The change from one *land use* category to another. Note that, in some scientific literature, land-use change encompasses changes in land-use categories as well as changes in land management. See also *Afforestation, Agriculture, Forestry and Other Land Use (AFOLU), Deforestation, Land use, land-use change and forestry (LULUCF), and Reforestation*.

Indirect land-use change (iLUC)

Land-use change outside the area of focus that occurs as a consequence of change in use or management of land within the area of focus, such as through market or policy drivers. For example, if agricultural land is diverted to *biofuel* production, forest clearance may occur elsewhere to replace the former agricultural production.

Latent heat flux The turbulent *flux* of heat from the Earth's surface to the *atmosphere* that is associated with evaporation or condensation of water vapour at the surface; a component of the surface energy budget.

Leakage The effects of policies that result in a displacement of the environmental impact, thereby counteracting the intended effects of the initial policies.

Leapfrogging The ability of developing countries to bypass intermediate technologies and jump straight to advanced clean technologies.

Lifecycle assessment (LCA) Compilation and evaluation of the inputs, outputs and the potential environmental impacts of a product or service throughout its lifecycle (ISO 2018).

Likelihood The chance of a specific outcome occurring, where this might be estimated probabilistically. Likelihood is expressed in this report using a standard terminology (Mastrandrea et al. 2010). See also *Agreement, Confidence, Evidence, and Uncertainty*.

Livelihood The resources used and the activities undertaken in order for people to live. Livelihoods are usually determined by the entitlements and assets to which people have access. Such assets can be categorised as human, social, natural, physical or financial.

Local knowledge (LK) The understandings and skills developed by individuals and populations, specific to the places where they live. Local knowledge informs decision-making about fundamental aspects of life, from day-to-day activities to longer-term actions. This knowledge is a key element of the social and cultural systems which influence observations of and responses to climate change;

it also informs *governance* decisions (UNESCO 2018). See also *Indigenous knowledge*.

Lock-in A situation in which the future development of a system, including *infrastructure*, technologies, investments, *institutions*, and behavioural norms, is determined or constrained ('locked in') by historic developments. See also *Path dependence*.

Long-lived greenhouse gases (LLGHGs) A set of well-mixed *greenhouse gases* with long atmospheric lifetimes. This set of compounds includes *carbon dioxide* (CO₂) and *nitrous oxide* (N₂O), together with some fluorinated gases. They have a warming effect on *climate*. These compounds accumulate in the *atmosphere* at decadal to centennial time scales, and their effect on *climate* hence persists for decades to centuries after their emission. On time scales of decades to a century already emitted emissions of long-lived climate forcers can only be abated by greenhouse gas removal (GGR).

Loss and Damage, and losses and damages Research has taken Loss and Damage (capitalised letters) to refer to political debate under the *United Nations Framework Convention on Climate Change (UNFCCC)* following the establishment of the Warsaw International Mechanism for Loss and Damage in 2013, which is to 'address loss and damage associated with impacts of climate change, including extreme events and slow onset events, in developing countries that are particularly vulnerable to the adverse effects of climate change.' Lowercase letters (losses and damages) have been taken to refer broadly to harm from (observed) impacts and (projected) risks, and can be economic or non-economic (Mechler et al. 2018).

Maladaptive actions (Maladaptation) Actions that may lead to increased risk of adverse climate-related outcomes, including via increased *greenhouse gas* (GHG) emissions, increased *vulnerability* to climate change, or diminished welfare, now or in the future. Maladaptation is usually an unintended consequence.

Malnutrition Deficiencies, excesses, or imbalances in a person's intake of energy and/or nutrients. The term malnutrition addresses three broad groups of conditions: undernutrition, which includes wasting (low weight-for-height), stunting (low height-for-age) and underweight (low weight-for-age); micronutrient-related malnutrition, which includes micronutrient deficiencies (a lack of important vitamins and minerals) or micronutrient excess; and overweight, obesity and diet-related noncommunicable diseases (such as heart disease, stroke, diabetes and some cancers) (WHO 2018). Micronutrient deficiencies are sometimes termed 'hidden hunger' to emphasise that people can be malnourished in the sense of deficient without being deficient in calories. Hidden hunger can apply even where people are obese.

Managed forest *Forests* subject to human interventions (notably silvicultural management such as planting, pruning, thinning), timber and fuelwood harvest, protection (fire suppression, insect suppression) and management for amenity values or conservation, with defined geographical boundaries (Ogle et al. 2018). See also *Managed land*.

[Note: For a discussion of the term 'forest' in the context of National GHG inventories, see the 2006 IPCC Guidelines for National GHG Inventories (IPCC 2006).]

Managed grassland Grasslands on which human interventions are carried out, such as grazing domestic livestock or hay removal.

Managed land In the context of national *greenhouse gas (GHG)* inventories under the *United Nations Framework Convention on Climate Change (UNFCCC)*, the 2006 IPCC Guidelines for National GHG Inventories (IPCC 2006) defines managed land 'where human interventions and practices have been applied to perform production, ecological or social functions'. IPCC (2006) defines *anthropogenic* GHG emissions and removals in the *LULUCF* sector as all those occurring on 'managed land'. The key rationale for this approach is that the preponderance of anthropogenic effects occurs on managed lands.

[Note: More details can be found in IPCC 2006 Guidelines for National GHG Inventories, Volume 4, Chapter 1.]

Market failure When private decisions are based on market prices that do not reflect the real scarcity of goods and services but rather reflect market distortions, they do not generate an efficient allocation of resources but cause welfare losses. A market distortion is any event in which a market reaches a market clearing price that is substantially different from the price that a market would achieve while operating under conditions of perfect competition and state enforcement of legal contracts and the ownership of private property. Examples of factors causing market prices to deviate from real economic scarcity are environmental externalities, public goods, monopoly power, information asymmetry, transaction costs, and non-rational behaviour.

Material substitution Replacement of one material (including an energy carrier used as a feedstock) by another, due to scarcity, price, technological change, or because of lower environmental impacts or *greenhouse gas emissions*.

Measurement, Reporting and Verification (MRV)

Measurement

'Processes of data collection over time, providing basic datasets, including associated accuracy and precision, for the range of relevant variables. Possible data sources are field measurements, field observations, detection through remote sensing and interviews' (UN-REDD 2009).

Reporting

'The process of formal reporting of assessment results to the UNFCCC, according to predetermined formats and established standards, especially the Intergovernmental Panel on Climate Change (IPCC) Guidelines and GPG (Good Practice Guidance)' (UN-REDD 2009).

Verification

'The process of formal verification of reports, for example, the established approach to verify national communications and national inventory reports to the UNFCCC' (UN-REDD 2009).

Megacity Urban agglomerations with 10 million inhabitants or more. See also *City*.

Methane (CH₄) The *greenhouse gas (GHG)* methane is the major component of natural gas and associated with all hydrocarbon fuels. Significant *anthropogenic* emissions also occur as a result of animal husbandry and paddy rice production. Methane is also produced naturally where organic matter decays under anaerobic conditions, such as in wetlands. Under future *global warming*, there is potential for increased methane emissions from thawing permafrost, wetlands and sub-sea gas hydrates. See also *Short-lived climate forcers (SLCFs)*.

Migrant Any person who is moving or has moved across an international border or within a State away from his/her habitual place of residence, regardless of: (1) the person's legal status; (2) whether the movement is voluntary or involuntary; (3) what the causes for the movement are; or (4) what the length of the stay is (IOM 2018).

Migration (of humans) Movement of a person or a group of persons, either across an international border, or within a State. It is a population movement, encompassing any kind of movement of people, whatever its length, composition and causes; it includes migration of refugees, displaced persons, economic migrants, and persons moving for other purposes, including family reunification (IOM 2018).

Mitigation (of climate change) A human intervention to reduce emissions or enhance the *sinks* of *greenhouse gases*.

Mitigation measures In climate policy, mitigation measures are technologies, processes or practices that contribute to *mitigation*, for example, *renewable energy* technologies, waste minimisation processes, and public transport commuting practices.

Mitigation option A technology or practice that reduces *greenhouse gas* emissions or enhances *sinks*.

Mitigation pathways See *Pathways*.

Mitigation potential The quantity of net *greenhouse gas* emission reductions that can be achieved by a given *mitigation option* relative to specified emission baselines.

[Note: Net greenhouse gas emissions reduction is the sum of reduced emissions and/or enhanced *sinks*.]

See also *Sequestration potential*.

Biogeophysical potential

The mitigation potential constrained by biological, geophysical and geochemical limits and thermodynamics, without taking into account technical, social, economic and/or environmental considerations.

Economic potential

The portion of the technical potential for which the social benefits exceed the social costs, taking into account a social discount rate and the value of externalities.

Technical potential

The mitigation potential constrained by biogeophysical limits as well as availability of technologies and practices. Quantification of technical potentials takes into account primarily technical considerations, but social, economic and/or environmental considerations are occasionally also included, if these represent strong barriers for the deployment of an option.

Mitigation scenario See *Scenario*.

Multi-level governance See *Governance*.

Narrative See *Storyline*.

Nature's contributions to people (NCP) All the contributions, both positive and negative, of living nature (i.e., diversity of organisms, *ecosystems*, and their associated ecological and evolutionary processes) to the quality of life for people. Beneficial contributions from nature include such things as food provision,

water purification, flood control, and artistic inspiration, whereas detrimental contributions include disease transmission and predation that damages people or their assets. Many NCP may be perceived as benefits or detriments depending on the cultural, temporal or spatial context (Díaz et al. 2018). See also *Ecosystem services*.

Nature-based solutions Actions to protect, sustainably manage and restore natural or modified ecosystems that address societal challenges effectively and adaptively, simultaneously providing human well-being and biodiversity benefits (IUCN 2016). See also *Biodiversity* and *Ecosystem*.

Net negative greenhouse gas emissions A situation of net negative greenhouse gas emissions is achieved when metric-weighted *anthropogenic greenhouse gas (GHG)* removals exceed metric-weighted anthropogenic GHG emissions. Where multiple GHG are involved, the quantification of net emissions depends on the metric chosen to compare emissions of different gases (such as *global warming potential*, global temperature change potential, and others, as well as the chosen time horizon). See also *Carbon dioxide removal (CDR)*, *Greenhouse gas emission metric*, *Net-zero CO₂ emissions*, *Net-zero greenhouse gas emissions*, and *Negative greenhouse gas emissions*.

Net-zero CO₂ emissions Condition in which *anthropogenic carbon dioxide (CO₂)* emissions are balanced by anthropogenic CO₂ removals over a specified period.

[Note: *Carbon neutrality* and net-zero CO₂ emissions are overlapping concepts. The concepts can be applied at global or sub-global scales (e.g., regional, national and sub-national). At a global scale, the terms *carbon neutrality* and net-zero CO₂ emissions are equivalent. At sub-global scales, net-zero CO₂ emissions is generally applied to emissions and removals under direct control or territorial responsibility of the reporting entity, while *carbon neutrality* generally includes emissions and removals within and beyond the direct control or territorial responsibility of the reporting entity. Accounting rules specified by GHG programmes or schemes can have a significant influence on the quantification of relevant CO₂ emissions and removals.]

See also *Carbon neutrality*, *Land use, land-use change and forestry (LULUCF)* and *Net-zero greenhouse gas emissions*.

Net-zero greenhouse gas emissions Condition in which metric-weighted *anthropogenic greenhouse gas (GHG)* emissions are balanced by metric-weighted anthropogenic GHG removals over a specified period. The quantification of net-zero GHG emissions depends on the *GHG emission metric* chosen to compare emissions and removals of different gases, as well as the time horizon chosen for that metric.

[Note 1: Greenhouse gas neutrality and net-zero GHG emissions are overlapping concepts. The concept of net-zero GHG emissions can be applied at global or sub-global scales (e.g., regional, national and sub-national). At a global scale, the terms GHG neutrality and net-zero GHG emissions are equivalent. At sub-global scales, net-zero GHG emissions is generally applied to emissions and removals under direct control or territorial responsibility of the reporting entity, while GHG neutrality generally includes anthropogenic emissions and anthropogenic removals within and beyond the direct control or territorial responsibility of the reporting entity. Accounting rules specified by GHG programmes or schemes can have a significant influence on the quantification of relevant emissions and removals.]

Note 2: Under the Paris Rulebook (Decision 18/CMA.1, annex, paragraph 37), parties have agreed to use GWP100 values from the IPCC AR5 or GWP100 values from a subsequent IPCC Assessment Report to report aggregate emissions and removals of GHGs. In addition, parties may use other metrics to report supplemental information on aggregate emissions and removals of GHGs.]

See also *Greenhouse gas neutrality*, *Net-zero CO₂ emissions*, and *Land use, land-use change and forestry (LULUCF)*.

Nitrous oxide (N₂O) The main *anthropogenic* source of N₂O, a *greenhouse gas (GHG)*, is agriculture (soil and animal manure management), but important contributions also come from sewage treatment, *fossil fuel* combustion, and chemical industrial processes. N₂O is also produced naturally from a wide variety of biological sources in soil and water, particularly microbial action in wet tropical *forests*.

Non-overshoot pathways See *Pathways*.

Ocean alkalisation/Ocean alkalinity enhancement A proposed *carbon dioxide removal (CDR)* method that involves deposition of alkaline minerals or their dissociation products at the ocean surface. This increases surface total alkalinity, and may thus increase ocean *carbon dioxide (CO₂)* uptake and ameliorate surface ocean acidification. See also *Anthropogenic removals*.

Ocean fertilisation A proposed *carbon dioxide removal (CDR)* method that relies on the deliberate increase of nutrient supply to the near-surface *ocean* with the aim of *sequestering* additional CO₂ from the *atmosphere* through biological production. Methods include direct addition of micro-nutrients or macro-nutrients. To be successful, the additional carbon needs to reach the deep ocean where it has the potential to be sequestered on climatically relevant time scales. See also *Anthropogenic removals*.

Offset (in climate policy) The reduction, avoidance or removal of a unit of *greenhouse gas (GHG)* emissions by one entity, purchased by another entity to counterbalance a unit of GHG emissions by that other entity. Offsets are commonly subject to rules and environmental integrity criteria intended to ensure that offsets achieve their stated mitigation outcome. Relevant criteria include, but are not limited to, the avoidance of double counting and *leakage*, use of appropriate baselines, *additionality*, and permanence or measures to address impermanence. See also *Greenhouse gas emission metric* and *Carbon neutrality*.

Organic farming An agricultural production system that aims to utilise natural processes and cycles to limit off-farm and notably synthetic inputs, while also aiming to enhance agroecosystems and society. Organic farming is often legally defined and governed by standards, typically guided by principles outlined by the International Federation of Organic Agriculture Movements (IFOAM – Organics International) (IFOAM – Organics International 2014).

Overshoot pathways See *Pathways*.

Ozone (O₃) The triatomic form of oxygen, and a gaseous *atmospheric* constituent. In the troposphere, O₃ is created both naturally and by photochemical reactions involving gases resulting from human activities (e.g., smog). Tropospheric O₃ acts as a *greenhouse gas (GHG)*. In the stratosphere, O₃ is created by the interaction between solar ultraviolet radiation and molecular oxygen

(O₂). Stratospheric O₃ plays a dominant role in the stratospheric radiative balance. Its concentration is highest in the ozone layer.

Pareto optimum A state in which no one's welfare can be increased without reducing someone else's welfare.

Participatory governance See *Governance*.

Particulate matter (PM) Atmospheric aerosols involved in air pollution issues. Of greatest concern for health are particles of aerodynamic diameter less than or equal to 10 micrometers, usually designated as PM₁₀ and particles of diameter less than or equal to 2.5 micrometers, usually designated as PM_{2.5}.

Path dependence The generic situation where decisions, events, or outcomes at one point in time constrain *adaptation*, *mitigation*, or other actions or options at a later point in time. See also *Lock-in*.

Pathways The temporal evolution of natural and/or human systems towards a future state. Pathway concepts range from sets of quantitative and qualitative *scenarios* or narratives of potential futures to solution-oriented decision-making processes to achieve desirable societal goals. Pathway approaches typically focus on biophysical, techno-economic, and/or socio-behavioural trajectories and involve various dynamics, goals, and actors across different scales. See also *Scenario* and *Storyline*.

1.5°C pathway

A pathway of emissions of *greenhouse gases* and other climate *forcers* that provides an approximately one-in-two to two-in-three chance, given current knowledge of the climate response, of global warming either remaining below 1.5°C or returning to 1.5°C by around 2100 following an overshoot.

Adaptation pathways

A series of *adaptation* choices involving trade-offs between short-term and long-term goals and values. These are processes of deliberation to identify solutions that are meaningful to people in the context of their daily lives and to avoid potential *maladaptation*.

Climate-resilient pathways

Iterative processes for managing change within complex systems in order to reduce disruptions and enhance opportunities associated with climate change.

Development pathways

Development pathways evolve as the result of the countless decisions being made and actions being taken at all levels of societal structure, as well due to the emergent dynamics within and between institutions, cultural norms, technological systems and other drivers of behavioural change.

See also *Shifting development pathways (SDPs)* and *Shifting development pathways to sustainability (SDPS)*.

Emission pathways

Modelled trajectories of global *anthropogenic emissions* over the 21st century.

Mitigation pathways

A temporal evolution of a set of *mitigation scenario* features, such as *greenhouse gas* emissions and socio-economic development.

Non-overshoot pathways

Pathways that stay below a specified concentration, *forcing*, or global warming level during a specified period of time (e.g., until 2100).

Overshoot pathways

Pathways that first exceed a specified concentration, *forcing*, or global warming level, and then return to or below that level again before the end of a specified period of time (e.g., before 2100). Sometimes the magnitude and likelihood of the overshoot is also characterised. The overshoot duration can vary from one pathway to the next, but in most overshoot pathways in the literature and referred to as overshoot pathways in the AR6, the overshoot occurs over a period of at least one decade and up to several decades.

Representative Concentration Pathways (RCPs)

Scenarios that include time series of *emissions* and concentrations of the full suite of *greenhouse gases (GHGs)* and *aerosols* and chemically active gases, as well as *land use/land cover* (Moss et al. 2010). The word representative signifies that each RCP provides only one of many possible scenarios that would lead to the specific *radiative forcing* characteristics. The term pathway emphasises that not only the long-term concentration levels are of interest, but also the trajectory taken over time to reach that outcome (Moss et al. 2010).

RCPs usually refer to the portion of the concentration pathway extending up to 2100, for which *integrated assessment models* produced corresponding emission scenarios. Extended concentration pathways describe extensions of the RCPs from 2100 to 2300 that were calculated using simple rules generated by stakeholder consultations, and do not represent fully consistent scenarios. Four RCPs produced from integrated assessment models were selected from the published literature and used in the Fifth IPCC Assessment, and are also used in this Assessment for comparison, spanning the range from approximately below 2°C warming to high (>4°C) warming best-estimates by the end of the 21st century: RCP2.6, RCP4.5 and RCP6.0 and RCP8.5.

- RCP2.6: One pathway where radiative forcing peaks at approximately 3 W m⁻² and then declines to be limited at 2.6 W m⁻² in 2100 (the corresponding Extended Concentration Pathway, or ECP, has constant emissions after 2100).
- RCP4.5 and RCP6.0: Two intermediate stabilisation pathways in which radiative forcing is limited at approximately 4.5 W m⁻² and 6.0 W m⁻² in 2100 (the corresponding ECPs have constant concentrations after 2150).
- RCP8.5: One high pathway which leads to >8.5 W m⁻² in 2100 (the corresponding ECP has constant emissions after 2100 until 2150 and constant concentrations after 2250).

See also *Shared socio-economic pathways (SSPs)* (under *Pathways*).

Shared Socio-economic Pathways (SSPs)

SSPs have been developed to complement the *Representative Concentration Pathways (RCPs)*. By design, the RCP emission and concentration pathways were stripped of their association with a certain socio-economic development. Different levels of *emissions* and *climate change* along the dimension of the RCPs can hence be explored against the backdrop of different socio-economic development pathways (SSPs) on the other dimension in a matrix. This integrative SSP-RCP framework is now widely used in the climate *impact* and policy analysis literature, where *climate projections*

obtained under the RCP scenarios are analysed against the backdrop of various SSPs. As several emission updates were due, a new set of emission scenarios was developed in conjunction with the SSPs. Hence, the abbreviation SSP is now used for two things: On the one hand SSP1, SSP2, ..., SSP5 are used to denote the five socio-economic scenario families. On the other hand, the abbreviations SSP1-1.9, SSP1-2.6, ..., SSP5-8.5 are used to denote the newly developed emission scenarios that are the result of an SSP implementation within an integrated assessment model. Those SSP scenarios are bare of climate policy assumption, but in combination with so-called shared policy assumptions (SPAs), various approximate *radiative forcing* levels of 1.9, 2.6, ..., or 8.5 W m⁻² are reached by the end of the century, respectively.

Transformation pathways

Trajectories describing consistent sets of possible futures of *greenhouse gas (GHG)* emissions, atmospheric concentrations, or *global mean surface temperatures* implied from mitigation and adaptation actions associated with a set of broad and irreversible economic, technological, societal, and behavioural changes. This can encompass changes in the way energy and infrastructure are used and produced, natural resources are managed and institutions are set up, and in the pace and direction of technological change.

Peri-urban areas Dynamic transition zones that have intense interaction between rural and *urban* economies, activities, households, and lifestyles. Neither fully rural or urban (Seto et al. 2010).

Policies (for climate change mitigation and adaptation)

Strategies that enable actions to be undertaken to accelerate *adaptation* and *mitigation*. Policies include those developed by national and subnational public agencies, and with the private sector. Policies for adaptation and mitigation often take the form of economic incentives, regulatory instruments, and decision-making and engagement processes.

Political economy The set of interlinked relationships between people, the state, society and markets as defined by law, politics, economics, customs and power that determine the outcome of trade and transactions and the distribution of wealth in a country or economy.

Pool, carbon and nitrogen A reservoir in the Earth System where elements, such as carbon and nitrogen, reside in various chemical forms for a period of time. See also *Sequestration*, *Sink*, *Source* and *Uptake*.

Poverty A complex concept with several definitions stemming from different schools of thought. It can refer to material circumstances (such as need, pattern of deprivation or limited resources), economic conditions (such as standard of living, *inequality* or economic position) and/or social relationships (such as social class, dependency, exclusion, lack of basic security or lack of entitlement).

Poverty eradication A set of measures to end poverty in all its forms everywhere. See also *Sustainable Development Goals (SDGs)*.

Precursors Atmospheric compounds that are not *greenhouse gases (GHGs)* or *aerosols*, but that have an effect on GHG or aerosol concentrations by taking part in physical or chemical processes regulating their production or destruction rates.

Pre-industrial (period) The multi-century period prior to the onset of large-scale industrial activity around 1750. The *reference period* 1850–1900 is used to approximate pre-industrial *global mean surface temperature (GMST)*. See also *Industrial revolution*.

Primary energy The energy that is embodied in resources as they exist in nature (e.g., coal, biomass uranium, solar radiation, wind, ocean currents) (Grubler et al. 2012).

[Note: Primary energy is defined in several alternative ways. The method used in this report is the direct equivalent method, which counts one unit of secondary energy provided from non-combustible sources as one unit of primary energy. For more details on the methodology, see Section 7 in Working Group III Annex II.]

See also *Final energy*.

Primary production The synthesis of organic compounds by plants and microbes, on land or in the ocean, primarily by photosynthesis using light and *carbon dioxide (CO₂)* as sources of energy and carbon respectively. It can also occur through chemosynthesis, using chemical energy, for example, in deep sea vents.

Private costs Costs carried by individuals, companies or other private entities that undertake an action, whereas *social costs* include additionally the external costs on the environment and on society as a whole. Quantitative estimates of both private and social costs may be incomplete, because of difficulties in measuring all relevant effects.

Production-based emissions Emissions released to the *atmosphere* for the production of goods and services by a certain entity (e.g., a person, firm, country, or region). See also *Consumption-based emissions*.

Projection A potential future evolution of a quantity or set of quantities, often computed with the aid of a model. Unlike predictions, projections are conditional on assumptions concerning, for example, future socio-economic and technological developments that may or may not be realised. See also *Climate projection*, *Pathways* and *Scenario*.

Prosumers A consumer that also produces energy and inputs energy to the system, for which it is an active agent in the energy system and market.

Radiative forcing The change in the net, downward minus upward, radiative flux (expressed in W m⁻²) due to a change in an external driver of *climate change*, such as a change in the concentration of *carbon dioxide (CO₂)*, the concentration of volcanic *aerosols* or in the output of the Sun. The stratospherically adjusted radiative forcing is computed with all tropospheric properties held fixed at their unperturbed values, and after allowing for stratospheric temperatures, if perturbed, to readjust to radiative-dynamical equilibrium. Radiative forcing is called instantaneous if no change in stratospheric temperature is accounted for. The radiative forcing once both stratospheric and tropospheric adjustments are accounted for is termed the 'effective radiative forcing'.

Rebound effect Phenomena whereby the reduction in energy consumption or emissions (relative to a baseline) associated with the implementation of *mitigation measures* in a jurisdiction is offset to some degree through induced changes in consumption, production, and prices within the same jurisdiction. The rebound effect is most typically ascribed to technological energy efficiency improvements.

Reducing Emissions from Deforestation and Forest Degradation (REDD+) REDD+ refers to reducing emissions from *deforestation*; reducing emissions from *forest* degradation; conservation of forest carbon stocks; sustainable management of forests; and enhancement of forest carbon stocks (see UNFCCC decision 1/CP.16, para. 70).

Reference period A time period of interest, or a period over which some relevant statistics are calculated. A reference period can be used as a *baseline period* or as a comparison to a baseline period.

Baseline period

A time period against which differences are calculated (e.g., expressed as anomalies relative to a baseline).

Reference scenario See *Scenario*.

Reforestation Conversion to *forest* of land that has previously contained forests but that has been converted to some other use.

[Note: For a discussion of the term forest and related terms such as *afforestation*, reforestation and *deforestation*, see the 2006 IPCC Guidelines for National Greenhouse Gas Inventories and their 2019 Refinement, and information provided by the United Nations Framework Convention on Climate Change (IPCC 2006, 2019; UNFCCC 2021a,b).]

See also *Anthropogenic removals*, *Carbon dioxide removal (CDR)* and *Reducing Emissions from Deforestation and Forest Degradation (REDD+)*.

Regenerative agriculture A universally agreed definition of this relatively new farming approach has yet to be established, but regenerative agriculture broadly refers to the implementation of varying combinations of agricultural management practices, to ensure the continued restoration and enhancement of soil health, *biodiversity* and *ecosystem* functioning, in conjunction with profitable agricultural production.

Region *Land* and/or *ocean* area characterised by specific geographical and/or climatological features. The *climate* of a region emerges from a multi-scale combination of its own features, remote influences from other regions, and global climate conditions.

Remaining carbon budget See *Carbon budget*.

Renewable energy (RE) Any form of energy that is replenished by natural processes at a rate that equals or exceeds its rate of use.

Variable renewable energy (VRE)

Renewable energy sources such as *wind* and *solar energy* whose output is determined by weather, in contrast to 'dispatchable' generators that adjust their output as a reaction to economic incentives. Variable renewables have also been termed intermittent, fluctuating, or non-dispatchable (Hirth 2013).

Representative Concentration Pathways (RCPs) See *Pathways*.

Resilience The capacity of interconnected social, economic and ecological systems to cope with a hazardous event, trend or disturbance, responding or reorganising in ways that maintain their essential function, identity and structure. Resilience is a positive attribute when it maintains capacity for *adaptation*, learning and/or transformation (Arctic Council 2016). See also *Hazard*, *Risk* and *Vulnerability*.

Resource cascade Tracking resource use (materials, energy, water, etc.), efficiency and losses through all conversion steps from primary resource extraction to various conversion steps, all the way to final service delivery.

Risk The potential for adverse consequences for human or ecological systems, recognising the diversity of values and objectives associated with such systems. In the context of *climate change*, risks can arise from potential *impacts* of climate change as well as human responses to climate change. Relevant adverse consequences include those on lives, *livelihoods*, health and *well-being*, economic, social and cultural assets and investments, *infrastructure*, services (including *ecosystem services*), *ecosystems* and species.

In the context of climate change impacts, risks result from dynamic interactions between climate-related *hazards* with the *exposure* and *vulnerability* of the affected human or ecological system to the hazards. Hazards, exposure and vulnerability may each be subject to uncertainty in terms of magnitude and *likelihood* of occurrence, and each may change over time and space due to socio-economic changes and human decision-making (see also *risk management*, *adaptation* and *mitigation*).

In the context of climate change responses, risks result from the potential for such responses not achieving the intended objective(s), or from potential trade-offs with, or negative side-effects on, other societal objectives, such as the *Sustainable Development Goals (SDGs)* (see also *risk trade-off*). Risks can arise, for example, from uncertainty in implementation, effectiveness or outcomes of *climate policy*, climate-related investments, technology development or adoption, and system transitions.

See also *Hazard* and *Impacts*.

Risk assessment The qualitative and/or quantitative scientific estimation of *risks*. See also *Risk management* and *Risk perception*.

Risk management Plans, actions, strategies or policies to reduce the *likelihood* and/or magnitude of adverse potential consequences, based on assessed or perceived *risks*. See also *Risk assessment*, and *Risk perception*.

Risk perception The subjective judgement that people make about the characteristics and severity of a *risk*. See also *Risk assessment*, and *Risk management*.

Risk trade-off The change in the portfolio of *risks* that occurs when a countervailing risk is generated (knowingly or inadvertently) by an intervention to reduce the target risk (Wiener and Graham 2009).

Sea surface temperature (SST) The subsurface bulk temperature in the top few metres of the ocean, measured by ships, buoys and drifters. From ships, measurements of water samples in buckets were mostly switched in the 1940s to samples from engine intake water. Satellite measurements of skin temperature (uppermost layer; a fraction of a millimetre thick) in the infrared or the top centimetre or so in the microwave are also used, but must be adjusted to be compatible with the bulk temperature.

Scenario A plausible description of how the future may develop based on a coherent and internally consistent set of assumptions about key driving forces (e.g., rate of technological change, prices)

and relationships. Note that scenarios are neither predictions nor forecasts, but are used to provide a view of the implications of developments and actions.

Baseline scenario

See [Reference Scenario](#) (under [Scenario](#)).

Concentrations scenario

A plausible representation of the future development of atmospheric concentrations of substances that are radiatively active (e.g., [greenhouse gases](#), [aerosols](#), tropospheric [ozone](#)), plus human-induced [land cover changes](#) that can be radiatively active via [albedo](#) changes, and often used as input to a [climate model](#) to compute [climate projections](#).

Emissions scenario

A plausible representation of the future development of emissions of substances that are radiatively active (e.g., [greenhouse gases](#) or [aerosols](#)), plus human-induced land-cover changes that can be radiatively active via [albedo](#) changes, based on a coherent and internally consistent set of assumptions about driving forces (such as demographic and socio-economic development, technological change, energy and [land use](#)) and their key relationships. [Concentration scenarios](#), derived from emission scenarios, are often used as input to a [climate model](#) to compute [climate projections](#).

Mitigation scenario

A plausible description of the future that describes how the (studied) system responds to the implementation of [mitigation](#) policies and measures.

Reference scenario

Scenario used as starting or reference point for a comparison between two or more scenarios.

[Note 1: In many types of [climate change](#) research, reference scenarios reflect specific assumptions about patterns of socio-economic development and may represent futures that assume no climate policies or specified climate policies, for example, those in place or planned at the time a study is carried out. Reference scenarios may also represent futures with limited or no climate impacts or adaptation, to serve as a point of comparison for futures with impacts and adaptation. These are also referred to as ‘baseline scenarios’ in the literature.]

Note 2: Reference scenarios can also be climate policy or impact scenarios, which in that case are taken as a point of comparison to explore the implications of other features, for example, of delay, technological options, policy design and strategy or to explore the effects of additional impacts and adaptation beyond those represented in the reference scenario.

Note 3: The term [business as usual](#) scenario has been used to describe a scenario that assumes no additional policies beyond those currently in place, and where patterns of socio-economic development are consistent with recent trends. The term is now used less frequently than in the past.

Note 4: In climate change attribution or impact attribution research reference scenarios may refer to counterfactual historical scenarios assuming no anthropogenic [greenhouse gas \(GHG\)](#) emissions (climate change attribution) or no climate change (impact attribution).]

Socio-economic scenario

A scenario that describes a plausible future in terms of population, [gross domestic product \(GDP\)](#), and other socio-economic factors relevant to understanding the implications of [climate change](#).

Scenario storyline

 See [Storyline](#).

Sequestration The process of storing carbon in a carbon pool. See also [Pool](#), [carbon and nitrogen](#), [Sequestration potential](#), [Sink](#), [Soil carbon sequestration \(SCS\)](#), [Source](#), and [Uptake](#).

Sequestration potential The quantity of [greenhouse gases](#) that can be removed from the [atmosphere](#) by anthropogenic enhancement of [sinks](#) and stored in a pool. See [Mitigation potential](#) for different subcategories of sequestration potential. See also [Pool](#), [carbon and nitrogen](#), [Sequestration](#), [Sink](#), [Source](#), and [Uptake](#).

Service provisioning Various services (such as illumination and mobility) can be provided by ‘systems’ through the use of energy, materials, and other resources comprising: (i) Resource flows (e.g., energy); (ii) Technologies for resource use and energy conversion (e.g., vehicles and their engines); and (iii) Social/organisational forms of service delivery (e.g., publicly owned companies, or privately owned companies, e-commerce).

Services Activities that help satisfy human wants or needs. While they usually involve relationships between producers and consumers, services are less tangible and less storable than goods since they represent flows not stocks, and when their regeneration conditions are protected they may be reused over time.

Settlements Places of concentrated human habitation. Settlements can range from isolated rural villages to [urban regions](#) with significant global influence. They can include formally planned and informal or illegal habitation and related infrastructure. See also [Cities](#) and [Urban](#).

Shared policy assumptions (SPAs) See [Shared Socio-economic Pathways \(SSPs\)](#).

Shared Socio-economic Pathways (SSPs) See [Pathways](#).

Sharing economy A system which allows people to share goods and services by enabling collaborative use, access or ownership.

Shifting development pathways (SDPs) In this report, shifting development pathways describes transitions aimed at re-directing existing developmental trends. Societies may put in place [enabling conditions](#) to influence their future development pathways, when they endeavour to achieve certain outcomes. Some outcomes may be common, while others may be context-specific, given different starting points. See also [Development pathways](#) (under [Pathways](#)), and [Shifting development pathways to sustainability](#).

Shifting development pathways to sustainability Shifting development pathways to sustainability involves transitions aligned with a shared aspiration in the [Sustainable Development Goals \(SDGs\)](#) agreed globally, though sustainability may be interpreted differently in various contexts as societies pursue a variety of sustainable development objectives. See also [Development pathways](#) (under [Pathways](#)), and [Shifting development pathways \(SDPs\)](#).

Short-lived climate forcers (SLCFs) A set of chemically reactive compounds with short (relative to [carbon dioxide](#)) atmospheric

lifetimes (from hours to about two decades) but characterised by different physiochemical properties and environmental effects. Their emission or formation has a significant effect on radiative forcing over a period determined by their respective atmospheric lifetimes. Changes in their *emissions* can also induce long-term *climate* effects via, in particular, their interactions with some biogeochemical cycles. SLCFs are classified as direct or indirect, with direct SLCFs exerting climate effects through their *radiative forcing* and indirect SLCFs being the *precursors* of other direct climate forcers. Direct SLCFs include *methane* (CH₄), *ozone* (O₃), primary *aerosols* and some halogenated species. Indirect SLCFs are *precursors* of ozone or secondary aerosols. SLCFs can be cooling or warming through interactions with radiation and clouds. They are also referred to as near-term climate forcers. Many SLCFs are also air pollutants. A subset of exclusively warming SLCFs is also referred to as short-lived climate pollutants (SLCPs), including methane, ozone, and *black carbon* (BC).

Short-lived climate pollutants (SLCP) See *Short-lived climate forcers (SLCFs)*.

Simple climate model (SCM) A broad class of lower-dimensional models of the energy balance, radiative transfer, *carbon cycle*, or a combination of such physical components. SCMs are also suitable for performing emulations of climate-mean variables of Earth System Models (ESMs), given that their structural flexibility can capture both the parametric and structural uncertainties across process-oriented ESM responses. They can also be used to test consistency across multiple lines of evidence with regard to *climate sensitivity* ranges, *transient climate responses* (TCRs), *transient climate response to cumulative CO₂ emissions* (TCREs) and *carbon cycle* feedbacks. See also *Emulators*.

Sink Any process, activity or mechanism which removes a *greenhouse gas*, an *aerosol* or a *precursor* of a *greenhouse gas* from the *atmosphere* (UNFCCC Article 1.8 (UNFCCC 1992)). See also *Pool, carbon and nitrogen, Sequestration, Source* and *Uptake*.

Small Island Developing States (SIDS) SIDS, as recognised by the United Nations OHRLLS (UN Office of the High Representative for the Least Developed Countries, Landlocked Developing Countries and Small Island Developing States), are a distinct group of developing countries facing specific social, economic and environmental vulnerabilities (UN-OHRLLS 2011). They were recognised as a special case, both for their environment and development, at the Rio Earth Summit in Brazil in 1992. Fifty-eight countries and territories are presently classified as SIDS by the UN OHRLLS, with 38 being UN member states and 20 being non-UN members or associate members of the Regional Commissions (UN-OHRLLS 2018).

Smart grids A smart grid uses information and communications technology to gather data on the behaviours of suppliers and consumers in the production, distribution, and use of electricity. Through automated responses or the provision of price signals, this information can then be used to improve the efficiency, reliability, economics, and sustainability of the electricity network.

Social cost of carbon (SCC) The net present value of aggregate climate damages (with overall harmful damages expressed as a number with positive sign) from one more tonne of carbon in the

form of *carbon dioxide* (CO₂), conditional on a global emissions trajectory over time.

Social costs The full costs of an action in terms of social welfare losses, including external costs associated with the impacts of this action on the environment, the economy (*GDP*, employment) and on the society as a whole.

Social group A collective of people who share similar characteristics and collectively may have a sense of unity (Forsyth 2010).

Social identity The portion of an individual's self-concept derived from perceived membership in a relevant *social group* (Tajfel and Turner 1986).

Social inclusion A process of improving the terms of participation in society, particularly for people who are disadvantaged, through enhancing opportunities, access to resources, and respect for rights (UNDESA 2018).

Social infrastructure See *Infrastructure*.

Social learning A process of social interaction through which people learn new behaviours, capacities, values, and attitudes.

Social-ecological system An integrated system that includes human societies and *ecosystems*, in which humans are part of nature. The functions of such a system arise from the interactions and interdependence of the social and ecological subsystems. The system's structure is characterised by reciprocal feedbacks, emphasising that humans must be seen as a part of, not apart from, nature (Berkes and Folke 1998; Arctic Council 2016).

Socio-economic scenario See *Scenario*.

Socio-technical transitions Where technological change is associated with social systems and the two are inextricably linked.

Soil carbon sequestration (SCS) *Land management* changes which increase the *soil organic carbon* content, resulting in a net removal of *carbon dioxide* (CO₂) from the *atmosphere*. See also *Anthropogenic removals* and *Carbon dioxide removal (CDR)*.

Soil organic carbon Carbon contained in *soil organic matter*.

Soil organic matter The organic component of soil, comprising plant and animal residue at various stages of decomposition, and soil organisms.

Solar energy Energy from the Sun. Often the phrase is used to mean energy that is captured from solar radiation either as heat, as light that is converted into chemical energy by natural or artificial photosynthesis, or by photovoltaic panels and converted directly into electricity. See also *Renewable energy*.

Solar radiation modification (SRM) Refers to a range of radiation modification measures not related to *greenhouse gas* (GHG) mitigation that seek to limit *global warming*. Most methods involve reducing the amount of incoming solar radiation reaching the surface, but others also act on the longwave radiation budget by reducing optical thickness and cloud lifetime.

Source Any process or activity which releases a *greenhouse gas* (GHG), an *aerosol* or a *precursor* of a GHG into the *atmosphere*

(UNFCCC Article 1.9 (UNFCCC 1992)). See also *Sink*, *Pool*, *carbon and nitrogen*, *Sequestration*, *Sequestration Potential* and *Uptake*.

Spill-over effect The effects of domestic or sector mitigation measures on other countries or sectors. Spill-over effects can be positive or negative and include effects on trade, (carbon) *leakage*, transfer of innovations, and diffusion of environmentally sound technology and other issues.

Storyline A way of making sense of a situation or a series of events through the construction of a set of explanatory elements. Usually, it is built on logical or causal reasoning. In *climate* research, the term storyline is used both in connection to *scenarios* as related to a future trajectory of the climate and human systems or to a weather or climate event. In this context, storylines can be used to describe plural, conditional possible futures or explanations of a current situation, in contrast to single, definitive futures or explanations.

Scenario storyline

A narrative description of a *scenario* (or family of scenarios), highlighting the main scenario characteristics, relationships between key driving forces and the dynamics of their evolution.

Stranded assets Assets exposed to devaluations or conversion to 'liabilities' because of unanticipated changes in their initially expected revenues due to innovations and/or evolutions of the business context, including changes in public regulations at the domestic and international levels.

Subnational actors State/provincial, regional, metropolitan and local/municipal governments as well as non-party stakeholders, such as civil society, the private sector, *cities* and other subnational authorities, local communities and indigenous peoples.

Sufficiency A set of measures and daily practices that avoid demand for energy, materials, land and water while delivering human well-being for all within planetary boundaries.

Sustainability A dynamic process that guarantees the persistence of natural and human systems in an equitable manner.

Sustainable development (SD) Development that meets the needs of the present without compromising the ability of future generations to meet their own needs (WCED 1987) and balances social, economic and environmental concerns. See also *Development pathways* and *Sustainable Development Goals (SDGs)*.

Sustainable Development Goals (SDGs) The 17 global goals for development for all countries established by the United Nations through a participatory process and elaborated in the 2030 Agenda for Sustainable Development, including ending poverty and hunger; ensuring health and well-being, education, gender equality, clean water and energy, and decent work; building and ensuring resilient and sustainable infrastructure, cities and consumption; reducing inequalities; protecting land and water ecosystems; promoting peace, justice and partnerships; and taking urgent action on climate change. See also *Sustainable development*.

Sustainable forest management The stewardship and use of *forests* and forest lands in a way, and at a rate, that maintains their *biodiversity*, productivity, regeneration capacity, vitality and their potential to fulfil, now and in the future, relevant ecological,

economic and social functions, at local, national, and global levels, and that does not cause damage to other *ecosystems* (Forest Europe 1993).

Sustainable intensification (of agriculture) Increasing yields from the same area of land while decreasing negative environmental impacts of agricultural production and increasing the provision of environmental services (CGIAR 2019).

[Note: This definition is based on the concept of meeting demand from a finite land area, but it is scale-dependent. Sustainable intensification at a given scale (e.g., global or national) may require a decrease in production intensity at smaller scales and, in particular, places (often associated with previous, unsustainable, intensification) to achieve *sustainability* (Garnett et al. 2013).]

Sustainable land management The stewardship and use of *land* resources, including soils, water, animals and plants, to meet changing human needs, while simultaneously ensuring the long-term productive potential of these resources and the maintenance of their environmental functions (WOCAT, no date).

Systems of Innovation (SI) The set of public and private sector organisations (i.e., formally organised entities such as firms and universities; 'actors') and *institutions*, whose activities and interactions generate, modify and deploy new technologies. The SI approach has been used to understand and analyse innovation at the national, regional, and technological levels, and in transnational contexts (Lundvall 1992, 1988).

Technology deployment The act of bringing technology into effective application, involving a set of actors and activities to initiate, facilitate and/or support its implementation. See also *Technology diffusion*.

Technology diffusion The spread of a technology across different groups/users/markets over time. See also *Technology deployment* and *Technology transfer*.

Technology transfer The exchange of knowledge, hardware and associated software, money and goods among stakeholders, which leads to the spread of technology for *adaptation* or *mitigation*. The term encompasses both diffusion of technologies and technological cooperation across and within countries. See also *Technology diffusion*.

Teleconnection Association between *climate* variables at widely separated, geographically fixed locations related to each other through physical processes and oceanic and/or atmospheric dynamical pathways. Teleconnections can be caused by several climate phenomena, such as Rossby wave-trains, mid-latitude jet and storm track displacements, fluctuations of the Atlantic Meridional Overturning Circulation (AMOC), fluctuations of the Walker circulation, etc. They can be initiated by modes of climate variability, thus providing the development of remote climate anomalies at various temporal lags.

Temperature overshoot Exceedance of a specified global warming level, followed by a decline to or below that level during a specified period of time (e.g., before 2100). Sometimes the magnitude and likelihood of the overshoot is also characterised. The overshoot duration can vary from one *pathway* to the next, but in most *overshoot pathways* in the literature and as referred to as overshoot pathways in the AR6, the overshoot occurs over a period of at least one decade and up to several decades.

Tipping point A critical threshold beyond which a system reorganises, often abruptly and/or irreversibly. See also *Irreversibility*.

Total carbon budget See *Carbon budget*.

Trade-off A competition between different objectives within a decision situation, where pursuing one objective will diminish achievement of other objective(s). A trade-off exists when a policy or measure aimed at one objective (e.g., reducing *greenhouse gas* emissions) reduces outcomes for other objective(s) (e.g., *biodiversity* conservation, *energy security*) due to *adverse side effects*, thereby potentially reducing the net benefit to society or the environment. See also *Co-benefit*.

Transformation A change in the fundamental attributes of natural and human systems.

Transformation pathways See *Pathways*.

Transient climate response (TCR) See *Climate sensitivity*.

Transient climate response to cumulative CO₂ emissions (TCRE) See *Climate sensitivity*.

Transition The process of changing from one state or condition to another in a given period of time. Transition can occur in individuals, firms, cities, regions and nations, and can be based on incremental or transformative change.

Uncertainty A state of incomplete knowledge that can result from a lack of information or from disagreement about what is known or even knowable. It may have many types of sources, from imprecision in the data to ambiguously defined concepts or terminology, incomplete understanding of critical processes, or uncertain projections of *human behaviour*. Uncertainty can therefore be represented by quantitative measures (e.g., a probability density function) or by qualitative statements (e.g., reflecting the judgement of a team of experts) (Moss and Schneider 2000; Mastrandrea et al. 2010). See also *Confidence* and *Likelihood*.

United Nations Convention to Combat Desertification (UNCCD) A legally binding international agreement linking environment and development to sustainable land management, established in 1994. The Convention's objective is 'to combat desertification and mitigate the effects of drought in countries experiencing drought and/or desertification'. The Convention specifically addresses the arid, semi-arid and dry sub-humid areas, known as the drylands, and has a particular focus on Africa. As of September 2020, the UNCCD had 197 Parties. See also *Desertification*, *Drought* and *Land degradation*.

United Nations Framework Convention on Climate Change (UNFCCC) The UNFCCC was adopted in May 1992 and opened for signature at the 1992 Earth Summit in Rio de Janeiro. It entered into force in March 1994 and, as of September 2020, had 197 Parties (196 States and the European Union). The Convention's ultimate objective is the 'stabilisation of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system' (UNFCCC 1992). The provisions of the Convention are pursued and implemented by two further treaties: the Kyoto Protocol and the Paris Agreement.

Uptake The transfer of substances (such as carbon) or energy (e.g., heat) from one compartment of a system to another; for

example, in the Earth System from the atmosphere to the ocean or to the land. See also *Pool*, *carbon and nitrogen*, *Sequestration*, *Sequestration potential*, *Sink* and *Source*.

Urban The categorisation of areas as 'urban' by government statistical departments is generally based either on population size, population density, economic base, provision of services, or some combination of the above. *Urban systems* are networks and nodes of intensive interaction and exchange including capital, culture, and material objects. Urban areas exist on a continuum with rural areas and tend to exhibit higher levels of complexity, higher populations and population density, intensity of capital investment, and a preponderance of secondary (processing) and tertiary (service) sector industries. The extent and intensity of these features varies significantly within and between urban areas. Urban places and systems are open with much movement and exchange between more rural areas as well as other urban regions. Urban areas can be globally interconnected facilitating rapid flows between them – of capital investment, of ideas and culture, human migration, and disease. See also *Cities*, *Peri-urban areas*, and *Urbanisation*.

Urban heat island The relative warmth of a *city* compared with surrounding rural areas, associated with heat trapping due to land use, the configuration and design of the built environment, including street layout and building size, the heat-absorbing properties of urban building materials, reduced ventilation, reduced greenery and water features, and domestic and industrial heat emissions generated directly from human activities. See also *City region*, *Urban*, and *Urban System*.

Urban Systems Urban systems refer to two interconnected systems: first, the comprehensive collections of city elements with multiple dimensions and characteristics: a) encompass physical, built, socio-economic-technical, political, and ecological subsystems; b) integrate social agent/constituency/processes with physical structure and processes; and c) exist within broader spatial and temporal scales and governance and institutional contexts; and second, the global system of cities and towns. See also *City region*, and *Urban*.

Urbanisation Urbanisation is a multi-dimensional process that involves at least three simultaneous changes: (i) land-use change: transformation of formerly rural settlements or natural land into urban settlements; (ii) demographic change: a shift in the spatial distribution of a population from rural to urban areas; and (iii) infrastructure change: an increase in provision of infrastructure services including electricity, sanitation, etc. Urbanisation often includes changes in lifestyle, culture, and behaviour, and thus alters the demographic, economic, and social structure of both urban and rural areas (Stokes and Seto 2019; Seto et al. 2014; UNDESA 2018). See also *Urban*, and *Urban Systems*.

Variable renewable energy (VRE) See *Renewable energy*.

Vulnerability The propensity or predisposition to be adversely affected. Vulnerability encompasses a variety of concepts and elements including sensitivity or susceptibility to harm and lack of capacity to cope and adapt. See also *Exposure*, *Hazard* and *Risk*.

Well-being A state of existence that fulfils various human needs, including material living conditions, meaningful social and community relationships and quality of life, as well as the ability to pursue one's goals, to thrive, and feel satisfied with one's life. Ecosystem well-being refers to the ability of *ecosystems* to maintain their diversity and quality.

Eudaimonic

Relational well-being concept based on the premise that experiencing life purpose, challenges and growth leads to flourishing, self-realisation, personal expression, and full functioning (Niemi 2014; Lamb and Steinberger 2017).

Hedonic

Subjective well-being concept based on the idea that attaining pleasure and avoiding pain leads to happiness (Ryan and Deci 2001).

Wind energy Kinetic energy from airflow arising from the uneven heating of the Earth's surface. The wind's kinetic energy is converted to mechanical shaft energy and electricity by a wind turbine, a rotating machine. A wind farm, wind project, wind park, or wind power plant is a group of wind turbines interconnected to a common utility system through a system of transformers, distribution lines, and (usually) one substation. See also [Renewable energy](#).

Zero emissions commitment See [Climate change commitment](#).

AII

Annex II: Definitions, Units and Conventions

Coordinating Lead Author:

Alaa Al Khourdajie (United Kingdom/Syria)

Lead Authors:

Renée van Diemen (the Netherlands/United Kingdom), William F. Lamb (Germany/United Kingdom), Minal Pathak (India), Andy Reisinger (New Zealand), Stéphane de la Rue du Can (the United States of America), Jim Skea (United Kingdom), Raphael Slade (United Kingdom), Shreya Some (India), Linda Steg (the Netherlands)

This chapter should be cited as:

IPCC, 2022: Annex II: Definitions, Units and Conventions [Al Khourdajie, A., R. van Diemen, W.F. Lamb, M. Pathak, A. Reisinger, S. de la Rue du Can, J. Skea, R. Slade, S. Some, L. Steg (eds)]. In IPCC, 2022: *Climate Change 2022: Mitigation of Climate Change. Contribution of Working Group III to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* [P.R. Shukla, J. Skea, R. Slade, A. Al Khourdajie, R. van Diemen, D. McCollum, M. Pathak, S. Some, P. Vyas, R. Fradera, M. Belkacemi, A. Hasija, G. Lisboa, S. Luz, J. Malley, (eds.)]. Cambridge University Press, Cambridge, UK and New York, NY, USA. doi: 10.1017/9781009157926.021.

Table of Contents

Part I: Definitions and Units	1823
A.II.1 Classification Schemes for Countries and Areas	1823
A.II.2 Standard Units and Unit Conversions	1824
Part II: Conventions	1826
A.II.3 Levelised Cost Metrics	1826
A.II.4 Growth Rates	1827
A.II.5 Trends Calculations Between Years and Over Decades	1828
A.II.6 Primary Energy Accounting	1828
A.II.7 The Concept of Risk	1828
A.II.8 GHG Emission Metrics	1830
Part III: Emissions Datasets	1831

This annex on *Definitions, Units and Conventions* provides background information on material used in the Working Group III contribution to the Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report (AR6 WGIII). The material presented in this annex documents metrics and common datasets that are typically used across multiple chapters of the report. In a few instances there are no updates to what was adopted by WGIII during the production of the Fifth Assessment Report (AR5), in which case this annex refers to Annex II of AR5 (Krey et al. 2014).

The annex comprises four parts: Part I introduces standards, metrics and common definitions adopted in the report; Part II presents methods to derive or calculate certain quantities and identities used in the report; Part III provides more detailed background information about common data sources; and Part IV presents integrative methodologies used in the assessment. While this structure may help readers to navigate through the annex, it is not possible in all cases to unambiguously assign a certain topic to one of these parts, naturally leading to some overlap between the parts.

Part I: Definitions and Units

A.II.1 Classification Schemes for Countries and Areas

In this report, two different levels of classification are used as a standard to present the results of analysis. The basis for the classification is the UN Statistics Division *Standard Country or Area Codes for Statistical Use*, also known as the M49 Standard (UNSD 1999). This covers geographical regions and, at the time of the literature cut-off date, identified developed regions, developing regions and least developed countries.

The high-level classification has six categories (Table 1): one covering North America, Europe, and Australia, Japan and New Zealand, labelled 'developed countries', and five covering other countries, all classified as developing using the M49 standard at the cut-off date. The high-level classification is an expansion of the RC5 (Regional Categorisation 5) adopted in AR5 WGIII, with Africa and the Middle East now identified separately. The low-level classification (ten categories) divides developed countries into three geographical regions, and Asia and Pacific into three sub-regions.

The high- and low-level classification schemes reflect schemes used in many global models and statistical sources. Where the report synthesises data, only these standard classification schemes have been used. On occasions, the underlying literature may deviate from the standard classification scheme and direct citations may unavoidably refer to alternative classifications. This is dealt with on a case-by-case basis and does not imply any endorsement of the scheme used in the underlying literature by the IPCC or the authors of this report.

The detailed allocation of countries and areas to the low-level classification is shown in Section 1.1. Following AR5, the classification scheme deviates from the UN regional classification with the result that Annex I, Annex II and non-Annex I countries as defined under the UN Framework Convention on Climate Change (UNFCCC) are distinguished. Some Annex I countries in Western Asia and countries

in Eastern Europe which are not members of the European Union are allocated to Eastern Europe and West-Central Asia (EEA). In AR5, these formed part of the Economies in Transition group. The remainder of Western Asia (non-Annex I) is allocated to the Middle East.

Following the practice of the UN Statistics Division, we note that the designations employed and the presentation of material in this report do not imply the expression of any opinion by the United Nations, the IPCC or the authors of this report concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. The term 'country' as used in this material also refers, as appropriate, to territories or areas.

A.II.1.1 Low Level of Regional Groupings

Africa: Algeria, Angola, Benin, Botswana, Burkina Faso, Burundi, Côte d'Ivoire, Cabo Verde, Cameroon, the Central African Republic, Chad, the Comoros, the Congo, the Democratic Republic of the Congo, Djibouti, Egypt, Equatorial Guinea, Eritrea, Eswatini, Ethiopia, Gabon, the Gambia, Ghana, Guinea, Guinea-Bissau, Kenya, Lesotho, Liberia, Libya, Madagascar, Malawi, Mali, Mauritania, Mauritius, Morocco, Mozambique, Namibia, the Niger, Nigeria, Rwanda, São Tomé and Príncipe, Senegal, Seychelles, Sierra Leone, Somalia, South Africa, the South Sudan, the Sudan, Togo, Tunisia, Uganda, the United Republic of Tanzania, Zambia, Zimbabwe.

Middle East: Bahrain, Islamic Republic of Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, the State of Palestine, the Syrian Arab Republic, the United Arab Emirates, Yemen.

Latin America and Caribbean: Antigua and Barbuda, Argentina, the Bahamas, Barbados, Belize, Plurinational State of Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominica, the Dominican Republic, Ecuador, El Salvador, Grenada, Guatemala, Guyana, Haiti, Honduras, Jamaica, Mexico, Nicaragua, Panama, Paraguay, Peru, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines, Suriname, Trinidad and Tobago, Uruguay, Bolivarian Republic of Venezuela.

North America: Canada, the United States of America.

Eastern Asia: China, the Republic of Korea, the Democratic People's Republic of Korea, Mongolia.

Southern Asia: Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, Sri Lanka.

South-East Asia and Pacific: Brunei Darussalam, Cambodia, Cook Islands, Fiji, Indonesia, Kiribati, the Lao People's Democratic Republic, Malaysia, the Marshall Islands, Federated States of Micronesia, Myanmar, Nauru, Niue, Palau, Papua New Guinea, the Philippines, Samoa, Singapore, Solomon Islands, Thailand, Timor-Leste, Tonga, Tuvalu, Vanuatu, Viet Nam.

Europe: Albania, Andorra, Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czechia, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Monaco, Montenegro, the Netherlands,

North Macedonia, Norway, Poland, Portugal, Romania, San Marino, Serbia, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey, the United Kingdom of Great Britain and Northern Ireland.

Australia, Japan, and New Zealand

Eastern Europe and West-Central Asia: Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Kyrgyzstan, the Republic of Moldova, the Russian Federation, Tajikistan, Turkmenistan, Ukraine, Uzbekistan.

International Shipping and Aviation

A.II.1.2 High, Low Levels of Regional Groupings

Table 1 | Classification schemes for countries and areas.

WGIII AR6	
High Level (6)	Low Level (10)
Developed Countries (DEV)	North America
	Europe
	Australia, Japan and New Zealand
Eastern Europe and West-Central Asia (EEA)	Eastern Europe and West-Central Asia
Latin America and Caribbean (LAM)	Latin America and Caribbean

Middle East (ME)	Middle East
Asia and Pacific (APC)	Eastern Asia
	Southern Asia
	South-East Asia and Pacific
International Shipping and Aviation	

A.II.2 Standard Units and Unit Conversions

The following sections introduce standard units and unit conversions used throughout this report.

A.II.2.1 Standard Units

Standard units of measurements include *Système International* (SI) units, SI-derived units, and other non-SI units as well the standard prefixes for basic physical units.

Table 2 | *Système International* (SI) units.

Physical quantity	Unit	Symbol
Length	metre	m
Mass	kilogram	kg
Time	second	s
Thermodynamic temperature	kelvin	K
Amount of substance	mole	mol

Table 3 | Special names and symbols for certain SI-derived units.

Physical quantity	Unit	Symbol	Definition
Force	Newton	N	kg m s ⁻²
Pressure	Pascal	Pa	kg m ⁻¹ s ⁻² (= N m ⁻²)
Energy	Joule	J	kg m ² s ⁻²
Power	Watt	W	kg m ² s ⁻³ (= J s ⁻¹)
Frequency	Hertz	Hz	s ⁻¹ (cycles per second)
Ionizing radiation dose	sievert	Sv	J kg ⁻¹

Table 4 | Non-SI standard units.

Monetary units	Unit	Symbol
Currency (market exchange rate, MER)	Constant US Dollar 2015	USD2015
Currency (purchasing power parity, PPP)	Constant International Dollar 2015	Int\$2015
Emission- and climate-related units	Unit	Symbol
Emissions	Metric tonnes	t
CO ₂ emissions	Metric tonnes CO ₂	tCO ₂
CO ₂ -equivalent emissions ¹	Metric tonnes CO ₂ -equivalent	tCO ₂ -eq
Abatement costs and emissions prices/taxes	Constant US dollar 2015 per metric tonne	USD2015 t ⁻¹
CO ₂ concentration or mixing ratio (μmol mol ⁻¹)	Parts per million (10 ⁶)	Ppm
CH ₄ concentration or mixing ratio (nmol mol ⁻¹)	Parts per billion (10 ⁹)	ppb
N ₂ O concentration or mixing ratio (nmol mol ⁻¹)	Parts per billion (10 ⁹)	ppb
Radiative forcing	Watts per square meter	W/m ²
Energy-related units	Unit	Symbol
Energy	Joule	J
Electricity and heat generation	Watt hours	Wh
Power (peak capacity)	Watt (Watt thermal, Watt electric)	W (Wth, We)
Capacity factor	Percent	%
Technical and economic lifetime	Years	yr
Specific energy investment costs	US dollar 2015 per kW (peak capacity)	USD2015/kW
Energy costs (e.g., LCOE) and prices	Constant US dollar 2015 per GJ or US cents 2015 per kWh	USD2015/GJ and USct2015/kWh
Passenger-distance	Passenger-kilometre	pkm
Payload-distance ²	Tonne-kilometre	tkm
Land-related units	Unit	Symbol
Area	Hectare	ha

Note that all monetary and monetary-related units are expressed in constant US Dollar 2015 (*USD*2015) or constant International Dollar 2015 (*Int*\$2015).

¹ A measure of aggregate greenhouse gas (GHG) emissions. This report uses the GHG metric Global Warming Potential with a time horizon of 100 years (GWP100); for details see Section 8.

² The is a unit of measure of freight transport which represents the transport of one tonne of goods (including packaging and tare weights of intermodal transport units) by a given transport mode (road, rail, air, sea, inland waterways, pipeline etc.) over a distance of one kilometre. The tonne measure here is not the same unit of measure as metric tonnes earlier in the third row of Table 4.

Table 5 | Prefixes for basic physical units.

Multiple	Prefix	Symbol	Fraction	Prefix	Symbol
1E+21	zeta	Z	1E-01	deci	d
1E+18	exa	E	1E-02	centi	c
1E+15	peta	P	1E-03	milli	m
1E+12	tera	T	1E-06	micro	μ
1E+09	giga	G	1E-09	nano	n

Giga watt hours	GWh	3.60E+00	8.60E+02	8.60E-05	1.23E-4	3.41E+03	1

In addition to the above physical units, datasets often report carbon emissions in either units of carbon (C) or carbon dioxide (CO₂). In this report we report carbon dioxide (CO₂) emissions where possible, using the conversion factor (44/12) to convert from units of C into CO₂. Finally, we note that the conversion from GJ to kWh is as follows: 1 GJ = ~277.78 kWh.

Where aggregate greenhouse gas emissions are reported, this report uses the Global Warming Potential with a time horizon of 100 years (GWP100); for details see Section 8.

A.II.2.3 Monetary Unit Conversion

To achieve comparability across cost and price information from different regions, where possible monetary quantities reported in the AR6 WGIII have been expressed in constant US Dollar 2015 (*USD2015*) or constant International Dollar 2015 (*Int\$2015*), as suitable.

To facilitate a consistent monetary unit conversion process, a simple and transparent procedure to convert different monetary units from the literature to *USD2015* is established and described below.

In order to convert from year *X* local currency unit (*LCU_x*) to 2015 US Dollars (*USD2015*) two steps are needed:

1. Inflating or deflating from year *X* to 2015, and
2. Converting from *LCU* to *USD*.

In practice, the order of applying these two steps will lead to different results. In this report, the conversion route adopted is *LCU_x* → *LCU2015* → *USD2015*, i.e., national or regional deflators are used to measure country- or region-specific inflation between year *X* and 2015 in local currency, then current (2015) exchange rates are used to convert to *USD2015*. The reason for adopting this route is when the economy's GDP deflator is used to convert to a common base year, that is, 2015, it captures the changes in prices of all goods and services that the economy produces. To convert from *LCU2015* to *USD2015*, the official 2015 exchange rates are used. Note that exchange rates often fluctuate significantly in the short term.

In order to be consistent with the choice of the World Bank databases as the primary source for gross domestic product (GDP) and other financial data throughout the report, deflators and exchange rates from the World Bank Development Indicators are used.³

To summarise, the following procedure has been adopted to convert monetary quantities reported in *LCU_x* to *USD2015*:

1. Use the country-/region-specific deflator and multiply with the deflator value to convert from *LCU_x* to *LCU2015*. In case national/regional data are reported in non-*LCU* units (e.g., *USD_x* or *Euro_x*), which is often the case in multi-national or global studies, apply the corresponding currency deflator to convert to 2015 currency (i.e., the US deflator and the Eurozone deflator in the examples above).

Example of converting GDP from *LCU2010* prices to *LCU2015* prices:

$$\begin{aligned} \text{GDP}_{2015} \text{ (in } LCU_{2015} \text{ prices)} &= \text{GDP}_{2010} \text{ (in } LCU_{2010} \text{ prices)} \\ &\quad * \frac{LCU_{2010} \text{ GDP deflator}}{LCU_{2015} \text{ GDP deflator}} \end{aligned}$$

2. Use the appropriate 2015 exchange rate to convert from *LCU2015* to *USD2015*.

Part II: Conventions

A.II.3 Levelised Cost Metrics

Across this report, a number of different metrics to characterise cost of climate change mitigation are employed. To facilitate a meaningful economic comparison across diverse options at the technology level, the metric of 'levelised costs' is used throughout several chapters of this report in various forms. The most used metrics are the levelised cost of energy (LCOE), the levelised cost of conserved energy (LCCE), and the levelised cost of conserved carbon (LCCC). These metrics are used throughout the AR6 WGIII to provide a benchmark for comparing different technologies or practices of achieving the respective output. Each comes with a set of context-specific caveats that need to be taken into account for correct interpretation. Various literature sources caution against drawing too strong conclusions from these metrics. Annex II in AR5, namely Section A.II.3.1, includes a detailed discussion on interpretations and caveats. Below is an introduction to each of these metrics and how they are derived.

A.II.3.1 Levelised Cost of Energy

The levelised cost of energy (LCOE) can be defined as the unique break-even cost-price where discounted revenues (price x quantities) are equal to the discounted net expenses (Moomaw et al. 2011), which is expressed as follows:

$$\sum_{t=0}^n \frac{E_t * LCOE}{(1+i)^t} = \sum_{t=0}^n \frac{Expenses_t}{(1+i)^t} \quad (1)$$

where E_t is the energy delivered in year t (might vary from year to year), expenses cover all (net) expenses in the year t , i is the discount rate and n the lifetime of the project.

solving for *LCOE*:

$$LCOE = \frac{\sum_{t=0}^n \frac{Expenses_t}{(1+i)^t}}{\sum_{t=0}^n \frac{E_t}{(1+i)^t}} \quad (2)$$

The lifetime expenses comprise investment costs I , operation and maintenance cost $O\&M$ (including waste management costs), fuel costs F , carbon costs C , and decommissioning costs D . In this case, levelised cost can be determined by (IEA 2010):

$$LCOE = \frac{\sum_{t=0}^n \frac{I_t + O\&M_t + F_t + C_t + D_t}{(1+i)^t}}{\sum_{t=0}^n \frac{E_t}{(1+i)^t}} \quad (3)$$

³ For instance, the data for GDP deflators for all countries can be downloaded following this link: <https://data.worldbank.org/indicator/NY.GDP.DEFL.ZS?locations=US>.

Assuming energy E provided annually is constant during the lifetime of the project, one can rewrite (3) as follows:

$$LCOE = \frac{CRF \cdot NPV(\text{Lifetime Expenses})}{E} = \frac{\text{Annuity}(\text{Lifetime Expenses})}{E} \quad (4)$$

where $CRF = \frac{i}{1 - (1 - i)^{-n}}$ is the capital recovery factor and NPV the net present value of all lifetime expenditures (Suerkemper et al. 2012).

For the simplified case, where the annual costs are also assumed constant over time, this can be further simplified to ($O\&M$ costs and fuel costs F constants):

$$LCOE = \frac{CRF \cdot I + O\&M + F}{E} \quad (5)$$

Where I is the upfront investment, $O\&M$ are the annual operation and maintenance costs, F are the annual fuel costs, and E is the annual energy provision. The investment I should be interpreted as the sum of all capital expenditures needed to make the investment fully operational discounted to $t = 0$. These might include discounted retrofit payments during the project lifetime and discounted decommissioning costs at the end of the lifetime. Where applicable, annual $O\&M$ costs have to take into account revenues for by-products and existing carbon costs must be added or treated as part of the annual fuel costs.

A.II.3.2 Levelised Cost of Conserved Energy

The levelised cost of conserved energy (LCCE) annualises the investment and operation and maintenance cost differences between a baseline technology and the energy-efficient alternative and divides this quantity by the annual energy savings.

The conceptual formula for $LCCE$ is essentially the same as Equation (4) above, with ΔE measuring in this context the amount of energy saved annually (Suerkemper et al. 2012):

$$LCCE = \frac{CRF \cdot NPV(\Delta \text{Lifetime Expenses})}{\Delta E} = \frac{\text{Annuity}(\Delta \text{Lifetime Expenses})}{\Delta E} \quad (6)$$

In the case of assumed annually constant $O\&M$ costs over the project lifetime, one can rewrite (6) as follows:

$$LCCE = \frac{CRF \cdot \Delta I + \Delta O\&M}{\Delta E} \quad (7)$$

where ΔI is the difference in investment costs of an energy saving measure (e.g., in USD) as compared to a baseline investment; $\Delta O\&M$ is the difference in annual operation and maintenance costs of an energy saving measure (e.g., in USD) as compared to the baseline in which the energy-saving measure is not implemented; ΔE is the annual energy conserved by the measure (e.g., in kWh) as compared

to the usage of the baseline technology; and CRF is the capital recovery factor depending on the discount rate and the lifetime of the measure in years as defined above. It should be stressed once more that this equation is only valid if $\Delta O\&M$ and ΔE are constant over the project lifetime. As $LCCE$ are designed to be compared with complementary levelised cost of energy supply, they do not include the annual fuel cost difference. Any additional monetary benefits that are associated with the energy-saving measure must be taken into account as part of the $O\&M$ difference.

A.II.3.3 Levelised Cost of Conserved Carbon

The levelised cost of conserved carbon can be used for comparing mitigation costs per unit of avoided carbon emissions and comparing these specific emission reduction costs for different options. This concept can be applied to other pollutants.

The conceptual formula for $LCCC$ is similar to Equation (6) above, with ΔC is the annual reduction in carbon emissions, which can be expressed as follows:

$$LCCC = \frac{CRF \cdot NPV(\Delta \text{Lifetime Expenses})}{\Delta C} = \frac{\text{Annuity}(\Delta \text{Lifetime Expenses})}{\Delta C} \quad (8)$$

In the case of assumed annually constant $O\&M$ costs over the lifetime, one can rewrite (8) as follows:

$$LCCC = \frac{CRF \cdot \Delta I + \Delta O\&M - \Delta B}{\Delta C} \quad (9)$$

where ΔI is the difference in investment costs of a mitigation measure (e.g., in USD) as compared to a baseline investment; $\Delta O\&M$ is the difference in annual operation and maintenance costs (e.g., in USD) and ΔB denotes the annual benefits, all compared to a baseline for which the option is not implemented. Note that annual benefits include reduced expenditures for fuels, if the investment project reduces emissions via a reduction in fuel use. As such $LCCC$ depend on energy prices. An important characteristic of this equation is that $LCCC$ can become negative if ΔB is bigger than the sum of the other two terms in the numerator.

A.II.4 Growth Rates

A.II.4.1 Emissions Growth Rates

In order to ensure consistency throughout the reported growth rates for emissions in AR6 WGIII, this section establishes the convention for calculating these rates.

The annual growth rate of emissions in percent per year for adjacent years is given by:

$$r = \frac{(E_{FF}(t_0 - 1) - E_{FF}(t_0))}{E_{FF}(t_0)} * 100 \quad (10)$$

where E_{FF} stands for fossil fuel CO₂ emissions, but can also be applied to other pollutants.

When relevant a leap-year adjustment is required in order to ensure valid interpretation of annual growth rates in the case of adjacent years. A leap-year affects adjacent years growth rate by approximately 0.3% yr^{-1} ($\frac{1}{365}$) which causes growth rates to go up approximately 0.3% if the first year is a leap year, and down 0.3% if the second year is a leap year (Friedlingstein et al. 2019).

The relative growth rate of E_{FF} over time periods of greater than one year is derived as follows.

Starting from:

$$E_{FF}(t+n) = E_{FF}(t) * (1+r)^n \quad (11)$$

solving for r :

$$r = \left(\frac{E_{FF}(t+n)}{E_{FF}(t)} \right)^{1/n} - 1 \quad (12)$$

A.II.4.2 Economic Growth Rates

A number of different methods exist for calculating economic growth rates (e.g., GDP), all of which lead to slightly different numerical results. If not stated otherwise, the annual growth rates shown in the report are derived using the *Log Difference Regression* technique or *Geometric Average* techniques which can be shown to be equivalent.

The Log Difference Regression growth rate r_{LD} is calculated as follows:

$$r_{LD} = e^{\beta} - 1 \text{ with } \beta = \frac{1}{T-1} \sum_{t=2}^T \Delta \ln X_t \quad (13)$$

The Geometric Average growth rate r_{GEO} is calculated as shown below:

$$r_{GEO} = \left(\frac{X_T}{X_1} \right)^{\frac{1}{T-1}} - 1 \quad (14)$$

Other methods that are used to calculate annual growth rates include the Ordinary Least Square technique and the Average Annual Growth Rate technique.

A.II.5 Trends Calculations Between Years and Over Decades

In order to compare or contrast trends between two different years, for instance comparing 2000 and 2010 cumulative CO₂ emissions, the year 2000 runs from 1st of January to 31st of December and similarly the year 2010 runs from 1st of January to 31st of December.

In order to undertake a timeseries calculation over a decade, the 10-year period should be defined as follows: from 1st of January 2001 to 31st of December 2010, that is 2001–2010.

A.II.6 Primary Energy Accounting

Primary energy accounting methods are used to report primary energy from non-combustible energy sources, in other words, nuclear energy and all renewable energy sources except biomass. Annex II of AR5, namely Section A.II.4, includes a detailed discussion of the three main methods dominant in the literature. The method adopted in AR6 is the *direct equivalent method* which counts one unit of secondary energy provided from non-combustible sources as one unit of primary energy, that is, 1 kWh of electricity or heat is accounted for as 1 kWh = 3.6 MJ of primary energy. This method is mostly used in the long-term scenarios literature, including multiple IPCC reports (IPCC 1995, Morita et al. 2001, Fisher et al. 2007, Fishedick et al. 2011), because it deals with fundamental transitions of energy systems that rely to a large extent on low-carbon, non-combustible energy sources.

A.II.7 The Concept of Risk

The concept of risk is a key aspect of how the IPCC assesses and communicates to decision-makers the potential adverse impacts of, and response options to, climate change. For the AR6 cycle, the definition of risk was revised (see below). Authors and IPCC Bureau members from all three Working Groups produced a Guidance (Reisinger et al. 2020) for authors on the concept of risk in order to ensure a consistent and transparent application across Working Groups.

This section summarises this Guidance briefly with a focus on issues related to WGIII, in other words, with focus on mitigation.

A.II.7.1 The Definition of Risk

Definition (see Annex I: Glossary):

Risk is the potential for adverse consequences for human or ecological systems, recognising the diversity of values and objectives associated with such systems. In the context of climate change, risks can arise from potential impacts of climate change as well as *human responses to climate change*. Relevant adverse consequences include those on lives, livelihoods, health and well-being, economic, social and cultural assets and investments, infrastructure, services (including ecosystem services), ecosystems and species.

- In the context of climate change impacts, risks result from dynamic interactions between climate-related hazards with the exposure and vulnerability of the affected human or ecological system to the hazards. Hazards, exposure and vulnerability may each be subject to uncertainty in terms of magnitude and likelihood of occurrence, and each may change over time and space due to socio-economic changes and human decision-making (see also risk management, adaptation, mitigation).

- In the context of climate change responses, risks result from the potential for such responses not achieving the intended objective(s), or from potential trade-offs with, or negative side-effects on, other societal objectives, such as the Sustainable Development Goals. Risks can arise for example from uncertainty in implementation, effectiveness or outcomes of climate policy, climate-related investments, technology development or adoption, and system transitions.

A.II.7.2 The Definition of Risk Management

Plans, actions, strategies or policies to reduce the likelihood and/or magnitude of adverse potential consequences, based on assessed or perceived risks (see also risk assessment, risk perception, risk transfer).

A.II.7.3 The Uses of the Term Risk and Risk Management

In this report, with the aim of improving the ability of decision-makers to understand and manage risk, the term is used when considering the potential for adverse outcomes and the uncertainty relating to these outcomes.

The term risk is not used as a simple substitute for probability or chance, to describe physical hazards, or as generic term for ‘anything bad that may happen in future’. While the probability of an adverse outcome does not necessarily have to be quantified, it needs to be characterised in some way to allow a risk assessment to inform responses via risk management.

In the AR6, risk refers to the potential for *adverse* consequences only. The term hazard is used where climatic events or trends has an identified potential for having adverse consequences to specific elements of an affected system. The contribution of Working Group I to the AR6 uses the more general term ‘climatic impact driver’ where a specific change in climate could have positive or negative consequences, and where a given climatic change may therefore act as a driver of risk or of an opportunity.

A.II.7.4 Examples of Application in the Context of Mitigation

Food Security

Climate-related risk to food security arises from multiple drivers that include both climate change impacts, responses to climate change and other stressors.

In the context of responses to climate change, drivers of risk include the demand for land from climate change responses (both adaptation and mitigation), the role of markets (e.g., price spikes related to biofuel demand in other countries), governance (how are conflicts about access to land and water resolved) and human behaviour more generally (e.g., trade barriers, dietary preferences).

Given the multitude of drivers, the risk to food security depends on assumptions about what drivers of risk are changing and which are

assumed to remain constant. Such assumptions are important for analytical robustness and are stated where relevant.

Risk in the Investment and Finance Literature

The investment and finance literature and practitioner community broadly distinguish between ‘physical risk’ and ‘transition risk’. The term ‘physical risk’ generally refers to risks arising from climate change impacts and climate-related hazards, while the term ‘transition risk’ typically refers to risks associated with the transition to a low carbon economy. These two types of risk may interact and create cascading or compounding risks.

Physical Risk

In much of the business and financial literature, the term ‘physical risk’ relates to those derived from the hazard × exposure × vulnerability framework. Physical risks arise from the potential for climate change impacts on the financial value of assets such as industrial plants or real estate, risks to facilities and infrastructure, impact on operations, water and raw material availability and supply chain disruptions. Physical risks have direct financial consequences for organisations where those risks are realised, as well as up-front insurance and investment related costs and downstream effects for users of relevant goods and services.

Transition Risk

Transition risks typically refer to risks associated with transition to a low carbon economy, which can entail extensive policy, legal, technology, and market changes to address mitigation and adaptation requirements related to climate change. Depending on the nature, speed, and focus of these changes, transition risks may pose varying levels of financial and reputational risk to organisations. Transition risks, if realised, can result in stranded assets, loss of markets, reduced returns on investment, and financial penalties, as well as adverse outcomes for governance and reputation.

A key issue is the stranding of assets that may not provide the expected financial returns and may end up as large financial liabilities.

Examples of types of transition risk relating to business, finance and investments:

- Risk related to an asset losing its value: the potential for loss of investment in infrastructure.
- Risk related to losing some or all of the principal of an investment (or invested capital).
- Solvency risk: the risk from reduction in credit ratings due to potential adverse consequences of climate change or climate policy. This includes liquidity risk or the risk of not being able to access funds. Another example is suffering a downgraded credit rating.
- Risk of lower-than-expected return on investment.
- Liability risk: lack of response to climate change creates risk of liability for failure to accurately assess risk of climate change to infrastructure and people.

- Technology risk: reliance on a particular technology to achieve an outcome creates the potential for adverse consequences if the technology fails to be developed or deployed.
- Policy risk: changes in policy or regulations in response to climate change could result in the loss of value of some assets.
- Market risk: changes in relative prices from increased prices of CO₂ for instance, could reduce financial returns and hence increase risks to investors.
- Residual risk: in parts of the financial literature, this concept refers to adverse consequences that cannot be quantified in probabilistic terms. Note that this is different from how the term 'residual risk' is generally used in IPCC, especially Working Group II, where it means the risk remaining after adaptation and risk reduction efforts.

A.II.8 GHG Emission Metrics

Comprehensive mitigation policy relies on consideration of all anthropogenic forcing agents, which differ widely in their atmospheric lifetimes and impacts on the climate system. GHG emission metrics⁴ provide simplified information about the effect that emissions of different GHGs have on global temperature or other aspects of climate, usually expressed relative to the effect of emitting CO₂. An assessment of different GHG emission metrics from a mitigation perspective is provided in Cross-Chapter Box 2 and Chapter 2 Supplementary Material, building on the assessment of GHG emission metrics from a physical science perspective in AR6 WGI (Forster et al., 2021, Section 7.6).

The WGIII contribution to the AR6 reports aggregate emissions and removals using updated values for the Global Warming Potential with a time horizon of 100 years (GWP100) from AR6 WGI unless stated otherwise. These updated GWP100 values reflect updated scientific understanding of the response of the climate system to emissions of different gases, and include a methodological update to incorporate climate-carbon cycle feedbacks associated with the emission of non-CO₂ gases (Forster et al. 2021). For the second-most important anthropogenic greenhouse gas, methane, the updated GWP100 value of 27 is similar but slightly lower than the value of 28 reported in the AR5 without climate-carbon cycle feedbacks. A full set of GWP100 values used in this report, based on the assessment of WGI (Forster et al. 2021, Section 7.6 and Table 7.SM.7), is provided in Table 9.

GWP100 was chosen in the WGIII contribution to the AR6 as the default GHG emissions metric for both procedural and scientific reasons.

Procedural reasons are to provide continuity with the use of GWP100 in past IPCC reports and the dominant use of GWP100 in the literature assessed by WGIII, and to match decisions made by Governments as part of the Paris Agreement Rulebook. Parties to the Paris Agreement decided to report aggregated emissions and removals (expressed as CO₂-eq) based on the Global Warming Potential with a time horizon of 100 years (GWP100), using values from IPCC AR5 or from a subsequent IPCC report as agreed upon by the CMA,⁵ and

to account for future nationally determined contributions (NDCs) in accordance with this approach. Parties may also report supplemental information on aggregate emissions and removals, expressed as CO₂-eq, using other GHG emission metrics assessed by the IPCC (4/CMA.1 and 18/CMA.1: UNFCCC 2019).

Scientific reasons for the use of GWP100 as default GHG emission metric in WGIII are that GWP100 approximates the relative damages caused by the two most important anthropogenic GHGs CO₂ and CH₄ for social discount rates around 3%. In addition, for pathways that limit warming to 2°C (>67%) or lower, using GWP100 to inform cost-effective abatement choices between gases would achieve these long-term temperature goals at close to least global cost within a few percent (*high confidence*) (see Cross-Chapter Box 2 in Chapter 2).

However, all emission metrics have limitations and uncertainties, given that they simplify the complexity of the physical climate system and its response to past and future GHG emissions. The most suitable metric for any given climate policy application, depends on judgements about the specific context, policy objectives and the way in which a metric would be used.

Wherever emissions, removals and mitigation potentials are expressed as CO₂-eq in this report, efforts have been made to recalculate those values consistently in terms of GWP100 values from AR6 WGI. However, in some cases it was not possible or feasible to disentangle conclusions from the existing literature into individual gases and then re-aggregate those emissions using updated GWP100 values. The existing literature assessed by WGIII uses a range of GWP100 values from previous IPCC reports; for CH₄, these values vary between 21 (based on the *IPCC Second Assessment Report*) to 28 or even 34 (based on the *IPCC Fifth Assessment Report* and depending on whether the study included or excluded climate-carbon cycle feedbacks). Consistent application of any metric is challenging as individual GHG emission species are not always provided in the literature assessed by WGIII. Where a full recalculation of CO₂-eq emissions or mitigation potentials into GWP100 AR6 values was not possible or feasible, and especially if non-CO₂ emissions constitute only a minor fraction of total emissions or abatement, individual chapters note this inconsistency and provide an indication of the potential magnitude of inconsistency.

To further reduce ambiguity regarding actual climate outcomes over time from any given set of emissions, the WGIII contribution to the AR6 reports emissions and mitigation options for individual gases where possible based on the available literature, and reports CO₂-eq emissions where this is judged to be policy relevant by author teams in addition to, not instead of individual gases.

⁴ Emission metrics also exist for aerosols, but these are not commonly used in climate policy. This assessment focuses on GHG emission metrics only.

⁵ The CMA is the Conference of the Parties serving as the meeting of the Parties to the Paris Agreement.

Table 9 | GWP100 values and atmospheric lifetimes for a range of GHGs, based on AR6 WGI (Forster et al. 2021).

Gas	AR6 – GWP100	Lifetime
CO ₂	1	N/A
CH ₄ (biogenic)	27.0	11.8
CH ₄ (fossil – combustion) ⁶	27.0	11.8
CH ₄ (fossil – fugitive and process)	29.8	11.8

Part III: Emissions Datasets

In this section we report on the historical emissions data used in the report (Section 9), the sectoral mapping on emissions sources (Section 9.1), the methane emissions sources (Section 9.2), and indirect emissions (Section 10).

A.II.9 Historical Data

Historic emissions data for countries, regions and sectors are presented throughout the report, but especially in Chapters 2, 6–7, 9–11, the Technical Summary and Summary for Policymakers. To ensure consistency and transparency we use the same emissions data across these chapters, with a single methodology, division of emissions sources, and following the classification scheme of countries and areas in Section 1 above.

Our primary data source is the Emissions Database for Global Atmospheric Research (EDGAR) (Crippa et al. 2021, Minx et al. 2021). This dataset provides annual CO₂, CH₄, N₂O and F-gas emissions on a country and emissions source level for the time span 1970 to 2019. The fossil fuel combustion component of EDGAR is closely linked to and sourced from International Energy Agency (IEA 2021) energy and emissions estimates. Section 2.2.1 in Chapter 2 of this report describes the differences between and coverage of different global emissions datasets.

In addition to EDGAR, land-use CO₂ emissions are sourced as the mean of three bookkeeping models, in a convention established by the Global Carbon Project (Friedlingstein et al. 2020) and consistent with the Working Group I approach. The bookkeeping models are BLUE (Bookkeeping of Land Use Emissions), Hansis et al. (2015), Houghton and Nassikas (2017) and OSCAR (Gasser et al. 2020).

Global total greenhouse gas emissions reported throughout AR6 are the sum of EDGAR and land-use CO₂ emissions. Significant uncertainties are associated with each gas and emissions source. These uncertainties are comprehensively treated in Section 2.2.1 of Chapter 2.

A.II.9.1 Mapping of Emission Sources to Sectors

The list below shows how emission sources in EDGAR are mapped to sectors throughout the AR6 WGIII. This defines unambiguous system boundaries for the sectors as represented in Chapters 6, 7 and 9–11 in the report and enables a discussion and representation of emission sources without double-counting.

Emission sources follows the definitions by the IPCC Task Force on National Greenhouse Gas Inventories (TFI) (IPCC 2019). EDGARv6 identifies each source as either 'Fossil' or 'Bio'. The 'Bio' label indicates the biomass component of fuel combustion, while 'Fossil' is the default label for all other emissions sources (including, for example, agricultural GHG emissions).

⁶ The biogenic CH₄ GWP100 value applies here, given Tier 1 IPCC CO₂ emissions factors which are based on total carbon content. The associated emissions are estimated on the bases of complete (100%) oxidation to CO₂ of carbon contained in combusted mass.

Table 10 | Mapping emission sources to sectors.

A.II.9.2 Methane Emissions Sources

In order to identify emission trends and mitigation opportunities by sector WGIII allocates each emission source to a sector and subsequently a subsector (check Section 9 above). These trends and mitigation opportunities are, in most cases and whenever possible, reported in the native unit of gases as well as in CO₂-eq using IPCC AR6 GWP100 values (Section 8). In the case of methane (CH₄), it has two different GWP100 values according to its source. The relevant sources of methane are: biogenic methane, fossil methane (source: combustion) and fossil methane (source: fugitive and process).

The majority of biogenic methane emissions result from the AFOLU sector due to livestock and other agricultural practices, but also from the energy systems, building, transport and industry (waste) sectors. Meanwhile, fossil methane (combustion) emissions result from electricity and heat generation in the energy systems sector as well as various combustion activities in all other sectors. Finally, fossil methane (fugitive and process) is emitted from the extraction and transportation of fossil fuels (fugitive methane), in addition to some activities in the industry sector (fugitive and process methane). See Table 12 below for a comprehensive list.

There are two GWP100 values assigned to methane depending on its source: a GWP100 value of 27 for biogenic methane and fossil methane (combustion), and a higher GWP100 value of 29.8 for fossil methane (fugitive and process), see Table 11 below. The difference between these two GWP100 values arises from treatment of the effect of methane conversion into CO₂ during its chemical decay in the atmosphere. The higher GWP100 value takes account of the warming caused by CO₂ that methane decays into, which adds to the warming caused by methane itself, while the lower GWP100 value does not.

In the case of biogenic methane, the correct GWP100 value is always the low value irrespective of the specific source. This is because all CO₂ originated from biomass is either already estimated and reported as CO₂ emissions from AFOLU sector, or in the case of short-rotation biomass, the original removal of CO₂ from the atmosphere is not reported and hence neither does the release of CO₂ back into the atmosphere need to be reported.

For fossil methane, the correct GWP100 value depends on the source, in other words, combustion source vs fugitive and process sources. Fossil methane (fugitive and process) should use the higher GWP100

value because CO₂ converted from methane in the atmosphere is not estimated anywhere else.

For fossil methane (combustion), despite it being fossil, the correct GWP100 value is always the low one, for the dataset reported here. This is due to the fact that the emissions data provider EDGAR (Section 9) considers a complete oxidation to CO₂ of all the carbon contained in the fossil fuel upon combustion, which is then reflected in the CO₂ emissions factors for the different sources based on the carbon content of fuels. In other words, IPCC (IPCC 2019) methods and defaults (Tier 1 IPCC CO₂ emissions factors) have been used where the associated CO₂ emissions are estimated on the basis of complete (100%) oxidation to CO₂ of carbon contained in combusted mass, which includes not only CO₂ directly released to the atmosphere but also CO₂ generated in the atmosphere from the carbon released as methane and converted to CO₂ only subsequently.

There are two exceptions applied to the above categorisation, both belong to the industry sector, sector codes 6Cb1 (Waste incineration – uncontrolled municipal solid waste (MSW) burning) and 6D (other waste). Uncontrolled MSW burning (6Cb1) includes both biogenic and fossil material, with incomplete oxidation for this source even when the IPCC Tier 1 default emission/oxidation factor is used. The GWP100 value adopted for this source is the low one, given that the fossil-origin methane component is unlikely to be very large. The 'other waste' (6D) source may also include both biogenic and fossil methane. However, it is unclear what type of waste handling is included here. Furthermore, the associated CO₂ emissions are not estimated. Therefore, the high GWP100 value is used.

In total, the estimation of EDGAR methane emissions in 2019 using a GWP100 value of 27 across all related sources results in 10.2 GtCO₂-eq, compared to 10.6 GtCO₂-eq using the higher GWP100 value as described. This is primarily driven by the readjustment of methane emissions from hard coal mining, gas production, and venting and flaring (sectors 1B1a1, 1B2b1 and 1B2c).

Table 11 | Summary of methane GWP100 values in AR6 depending on type and source.

CH ₄	GWP100 value
CH ₄ (biogenic)	27
CH ₄ (fossil – combustion)	27
CH ₄ (fossil – fugitive and process)	29.8

A.II.10 Indirect Emissions

Carbon dioxide emissions resulting from fuel combusted to produce electricity and heat are traditionally reported in the energy sector. An indirect emissions accounting principle allocates these emissions to the end-use sectors (industry, buildings, transport, and agriculture) where the electricity and heat are ultimately consumed. Attributing indirect emissions to consuming sectors makes it possible to assess the full potential impact of demand-side mitigation actions that reduce electricity and heat consumption (de la Rue du Can et al. 2015).

In order to estimate the indirect emissions of sectors and subsectors, the CO₂ Emissions from Fuel Combustion dataset of the International Energy Agency (IEA 2020a) is used. This database reports direct and indirect CO₂ emissions for IEA sectors, which are related to the IPCC (IPCC 2019) classification of emissions sources. The IEA adopted a new methodology in 2020 that is in line with the methodology used in Annex II of the WGIII contribution to AR5 (Krey et al. 2014), namely Section A.II.4. The IEA now estimates individual electricity and heat specific emission factors and allocates indirect emissions related to electricity and heat in the sectors where these forms of energy are used respectively (IEA 2020b). In order to estimate the share of energy input that results in the production of heat from the share that results in the production of electricity in Combined heat and Power plants, the IEA fixes the efficiency for heat production equal to 90%, which is the typical efficiency of a heat boiler and then allocates the remaining inputs to electricity production (IEA 2020b).

The base data for total global, regional and sectoral emissions in this report is the EDGAR database (see Section 9). Since there are some discrepancies between the electricity and heat emissions totals in EDGAR and IEA, we make some adjustments in order to estimate

indirect emissions in EDGAR using the IEA data. First, we match the sectors in EDGAR and IEA. Second, for each country and emissions source available in the IEA database, we take the IEA indirect emissions value and divide it by the total IEA value for electricity and heat. Third, we multiply these values through by the EDGAR value for electricity and heat. This procedure ensures that indirect emissions, in principle, sum to the correct total (EDGAR) value of electricity and heat that we use elsewhere in the reporting. However, total indirect emissions still do not sum to the total electricity and heat sector. This is due to an incomplete allocation of electricity and heat emissions in the IEA dataset, equal to 0.008 GtCO₂ in 2018, or about 0.06% of the total electricity and heat generation.

Additionally, a couple of adjustments were made to allocate emissions from IEA sector categories to IPCC categories from IPCC Task force definition as described in IPCC (2019) Guidelines (see Section 9). These include:

- Other non-specified sector: the IEA energy statistics report final energy and electricity use for three end-use sectors: industry, transport, and other. The 'other' category is further subdivided into agriculture, fishing, commercial and public services, residential, and non-specified other. The 'non-specified other' category includes energy used for agriculture, fishing, commercial and public services, and residential sectors that has not been allocated to these end-use sectors by the submitting countries. In most cases, there is no entry in the non-specified other category, indicating that all end-use energy consumption has been allocated to other end-use sectors. However, for some countries the energy reported in the non-specified other category needed to be allocated to the appropriate end-use sectors. To perform this allocation, the energy use in the non-specified

Table 13 | Feasibility dimensions and indicators to assess the barriers and enablers of implementing mitigation options.

Metric	Indicators
Geophysical feasibility	<ul style="list-style-type: none"> – Physical potential: physical constraints to implementation. – Geophysical resource availability (including geological storage capacity): availability of resources needed to implementation. – Land use: claims on land when option would be implemented.
Environmental-ecological feasibility	<ul style="list-style-type: none"> – Air pollution: increase or decrease in air pollutants, such as NH₄, CH₄ and fine dust. – Toxic waste, mining, ecotoxicity and eutrophication. – Water quantity and quality: changes in amount of water available for other uses, including groundwater. – Biodiversity: changes in conserved primary forest or grassland that affect biodiversity, and management to conserve and maintain land carbon stocks.
Technological feasibility	<ul style="list-style-type: none"> – Simplicity: is the option technically simple to operate, maintain and integrate. – Technology scalability: can the option be scaled up, quickly. – Maturity and technology readiness: R&D and time needed to implement to option.
Economic feasibility	<ul style="list-style-type: none"> – Costs now, in 2030 and in the long term, including investment costs, costs in USD tCO₂-eq⁻¹, and hidden costs. – Employment effects and economic growth.
Socio-cultural feasibility	<ul style="list-style-type: none"> – Public acceptance: extent to which the public supports the option and changes behavior accordingly. – Effects on health and well-being. – Distributional effects: equity and justice across groups, regions, and generations, including security of energy, water, food and poverty.
Institutional feasibility	<ul style="list-style-type: none"> – Political acceptance: extent to which politicians and governments support the option. – Institutional capacity and governance, cross-sectoral coordination: capability of institutions to implement and handle the option, and to coordinate it with other sectors, stakeholder and civil society. – Legal and administrative capacity: extent to which supportive legal and administrative changes can be achieved.

other category was allocated to the other end-use sectors based on the share of energy allocated to each of these sub-sectors for each region.

- Other energy industry own use: emissions from this category in the IEA statistics corresponds to the IPCC Source/Sink categories 1A1b and 1A1c (see Section 9) and contains emissions from fuel combusted in energy transformation industries that are not producing heat and/or power and therefore include oil refineries, coal mining, oil and gas extraction and other energy-producing industries. These emissions were not reallocated to the end use sectors where final products are ultimately consumed due to the lack of data.

Finally, it is also worth noting that indirect emissions only cover CO₂ emissions and that a small portion of non-CO₂ are not included in the IEA dataset and therefore have not been allocated to the end use sectors. Non-CO₂ emissions from total electricity and heat generation represents 0.55% of all GHG emissions from that sector.

Part IV: Assessment Methods

In this section we report on assessment methods adopted in the report. Section 11 describes the methodology adopted for assessing the feasibility of mitigation response options. Section 12 describes the methodology adopted for assessing synergies and trade-offs between mitigation options and the SDGs.

A.II.11 Methodology Adopted for Assessing the Feasibility of Mitigation Response Options

The feasibility assessment aims to identify barriers and enablers of the deployment of mitigation options and pathways. The assessment organises evidence to support decision making on actions and policies

that would improve the feasibility of mitigation options and pathways, by removing relevant barriers and strengthening enablers of change.

A.II.11.1 Feasibility of mitigation response options

The sectoral chapters in AR6 WGIII assess six dimensions of feasibility, with each dimension comprising a key set of indicators that can be evaluated by combining various strands of literature (see Table 13). The feasibility of systems-level changes is addressed in Chapter 3 of this report.

The sectoral chapters in this report assess to what extent the indicators in Table 13 would be enablers or barriers to implementation using the following scores (Nilsson et al. 2016):

- The indicator has a negative impact on the feasibility of the option, for example, it is associated with prohibitively high costs, levels of pollution or land use, or low public or political acceptance.
- ± Mixed evidence: the indicator has mixed positive and negative impacts on the feasibility of the option (e.g., more land use in some regions, while lower in other regions).
- + The indicator has a positive impact on the feasibility of the option, for example, it is associated with low costs, pollution, land use, or high public or political acceptance.
- 0/NA The indicator does not affect the feasibility of the option/criterion is not applicable for the option.
- NE No evidence available to assess the impact on the feasibility of the option.
- LE Limited evidence available to assess the impact on the feasibility the option.

A.II.11.2 Assessment

Each sectoral chapter assesses to what extent the indicators listed above would be an enabler or barrier to the implementation of selected mitigation options, by using the above scores. Then the total number of minus and plus points were computed, relative to the maximum possible number of points, per feasibility dimensions, for each option; a + counts as two plus points, a – as two minus points, and a \pm as one plus and one minus point. The resulting scores reveal the extent to which each feasibility dimension enables or inhibits the deployment of the relevant option, and indicates which type of additional effort would be needed to reduce or remove barriers as to improve the feasibility of relevant options.

The assessment is based on the literature, which is reflected in a line of sight. When appropriate, it is indicated whether the feasibility of an option varies across context (e.g., region), scale (e.g., small, medium, full scale), time (e.g., implementation in 2030 versus 2050) and warming level (e.g., 1.5°C versus 2°C).

Synergies and trade-offs may occur between the feasibility dimensions, and between specific mitigation options. Therefore, Chapters 3 and 4 employ a systems perspective and discuss the feasibility of mitigation scenarios and pathways in the long term and near to mid-term, respectively, on the basis of the feasibility assessments in the sectoral chapters taking into account such synergies and trade-offs. Chapter 5 (demand, services and social aspects of mitigation), Chapter 13 (national and sub-national policies and institutions), Chapter 14 (international cooperation), Chapter 15 (investment and finance) and Chapter 16 (innovation, technology development and transfer) address technological, economic, socio-cultural and institutional enabling conditions that can enhance the feasibility of options and remove relevant barriers.

A.II.12 Methodology Adopted for Assessing Synergies and Trade-offs Between Mitigation Options and the SDGs

Adopting climate mitigation options can generate multiple positive (synergies) and negative (trade-offs) interactions with sustainable development. Understanding these are crucial for selecting mitigation options and policy choices that maximise the synergies, minimise trade-offs, and potentially offset trade-offs (Roy et al. 2018). Chapter 5 in the IPCC's Special Report on Global Warming of 1.5°C examines the synergies and trade-offs of adaptation and mitigation measures with sustainable development and UN's Sustainable Development Goals (SDGs). Building on this, the sectoral chapters in the WGIII contribution to the AR6 include a qualitative assessment of the synergies and trade-offs between mitigation options in different sectors and the SDGs based on existing literature. All these assessments are collated and presented in Chapter 17 with a supplementary table including the details of the synergies and trade-offs with a line of sight (Section 17.3.3.7, Figure 17.1 and Supplementary Material Table 17.1). The assessment also recognises that interactions of mitigation options with the SDGs are

context-specific and therefore provides a detailed explanation in the supplementary table of Chapter 17.

For the assessment, the mitigation options were shortlisted from each of the sectoral chapters. The sectoral chapters assessed the literature in terms of the impacts of each of these mitigation options on the 17 SDGs. The assessment uses three signs:

- + to denote positive interaction only (synergies),
- to denote negative interaction only (trade-offs) and
- \pm to denote mixed interactions.

In some cases, where there is gap in literature, these are left blank denoting that these impacts have not been assessed in the literature included in the sectoral chapters. To support these signs, brief statements are provided followed by uncertainty qualifiers in the supplementary table of Chapter 17. These uncertainty qualifiers denote the confidence levels (low, medium and high).

Preamble

The use of scenarios and modelling methods are pillars in IPCC Working Group III (WGIII) Assessment Reports. Past WGIII assessment report cycles identified knowledge gaps about the integration of modelling across scales and disciplines, mainly between global integrated assessment modelling methods and bottom-up modelling insights of mitigation responses. The need to improve the transparency of model assumptions and enhance the communication of scenario results was also recognised.

This annex on *Scenarios and Modelling Methods* aims to address some of these gaps by detailing the modelling frameworks applied in the WGIII Sixth Assessment Report (AR6) chapters and disclose scenario assumptions and its key parameters. It has been explicitly included in the Scoping Meeting Report of the WGIII contribution to the AR6 and approved by the IPCC Panel at the 46th Session of the Panel.

The annex includes two parts: Part I on *Modelling Methods* summarises methods and tools available to evaluate sectoral, technological and behavioural mitigation responses as well as integrated assessment models (IAMs) for the analysis of ‘whole system’ transformation pathways; Part II on *Scenarios* sets out the portfolio of climate change scenarios and mitigation pathways assessed in the AR6 WGIII chapters, its underlying principles and interactions with scenario assessments by WGI and WGII.

Part I: Modelling Methods

A.III.1.1 Overview of Modelling Tools

Modelling frameworks vary vastly among themselves, and several key characteristics can be used as basis for model classification (Scrieciu et al. 2013; Dodds et al. 2015; Hardt and O’Neill 2017; Capellán-Pérez et al. 2020). Broadly, literature characterises models along three dimensions: (i) level of detail and heterogeneity, (ii) mathematical algorithm concepts, and (iii) temporal and spatial system boundaries (Krey 2014).

Commonly climate mitigation models are referred to as bottom-up and top-down depending upon their degree of detail (van Vuuren et al. 2009). Generally, bottom-up approaches present more systematic individual technological details about a reduced number of mitigation strategies of a specific sector or sub-sector. These models tend to disregard relations between specific sectors/technologies and miss evaluating interactions with the whole system. On the other hand, top-down approaches present a more aggregated and global analysis, in detriment of less detailed technological heterogeneity. They tend to focus on interactions within the whole system, such as market and policy instrument interactions within the global economy systems. Studies using top-down models are more capable of representing economic structural change than adopting technology-explicit decarbonisation strategies (van Vuuren et al. 2009; Kriegler et al. 2015a). Integrated assessment models (IAMs) typically use a top-down approach to model sectoral mitigation strategies.

Although this dichotomic classification has been mentioned in the literature, since the IPCC’s Fifth Assessment Report (AR5), climate mitigation models have evolved towards a more hybrid approach incorporating attributes of both bottom-up and top-down approaches. This is partly due to different modelling communities having different understandings of these two approaches’ principles, which can be misleading.

One of the most basic aspects of a modelling tool is how it approaches the system modelled from a solution perspective. A broad interpretation of mathematical algorithm concepts classifies models as simulation and optimisation models. **Simulation models** are based on the evaluation of the dynamic behaviour of a system (Lund et al. 2017). They can be used to determine the performance of a system under alternative options of key parameters in a plausible manner. Most often, simulation models require comprehensive knowledge of each parameter, in order to choose a specific path under several alternatives. On the other hand, **optimisation models** seek to maximise or minimise a mathematical objective function under a set of constraints (Baños et al. 2011; Iqbal et al. 2014). Most often, the objective function represents the total cost or revenue of a given system or the total welfare of a given society. One major aspect of optimisation models is that the solution is achieved by simultaneously binding a set of constraints, which can be used to represent real-life limitations on the system, such as: constraints on flows, resource and technology availability, labour and financial limitations, environmental aspects, and many other characteristics that the model may require (Fazlollahi et al. 2012; Pfenninger et al. 2014; Cedillos Alvarado et al. 2016). Specifically, when modelling climate mitigation responses, limiting carbon budgets is often used to represent future temperature level pathways (Rogelj et al. 2016; Millar et al. 2017; Peters 2018; Gidden et al. 2019).

Another major distinction among modelling tools is related to the solution methodology from a temporal perspective. They can have a perfect foresight intertemporal assumption or a recursive-dynamic assumption. Intertemporal optimisation with **perfect foresight** is an optimisation method for achieving an overall optimal solution over time. It is based on perfect information on all future states of a system and assumptions (such as technology availability and prices) and, as such, today’s and future decisions are made simultaneously, resulting in a single path of optimal actions that lead to the overall optimal solution (Keppo and Strubegger 2010; Gerbaulet et al. 2019). Such a modelling approach can present an optimal trajectory of the set of actions and policies that would lead to the overall first-best solution. However, real-life decisions are not always based on optimal solutions (Ellenbeck and Lilliestam 2019) and, therefore, solutions from perfect foresight models can be challenging to be implemented by policymakers (Pindyck 2013, 2017). For instance, perfect foresight implies perfect knowledge of the future states of the system, such as future demand for goods and products and availability of production factors and technology.

Recursive-dynamic models, also known as myopic or limited foresight models, make decisions over sequential periods of time. For each time step, the solution is achieved without information on future

time steps. Therefore, the solution path is a series of solutions in short trajectories that, ultimately, is very unlikely to achieve the overall optimal solution over the whole time period considered (Fuso Nerini et al. 2017). Nonetheless, the solution represents a set of possible and plausible policies and behavioural choices of the agents that could be taken in short-term cycles, without perfect information (Heuberger et al. 2018; Hanna and Gross 2020). In between, some models consider **imperfect or adaptive expectations**, where economic decisions are based on past, current and imperfectly anticipated future information (Keppo and Strubegger 2010; Kriegler et al. 2015a; Löffler et al. 2019). Modelling tools can also be differentiated by their level of representation of economic agents and sectors: they can have a full representation of all agents of the economy and their interactions with each other (**general equilibrium**) or focus on a more detailed representation of a subset of economic sectors and agents (**partial equilibrium**) (Cheng et al. 2015; Babatunde et al. 2017; Hanes and Carpenter 2017; Sanchez et al. 2018; Guedes et al. 2019; Pastor et al. 2019) (Annex III.I.2).

The most basic aspect to differentiate models is their main objective function, which includes the detail at which they represent key sectors, systems and agents. This affects the decision on methodology and other coverage aspects. Several models have been developed for different sectoral representation, such as the energy (Annex III.I.3), buildings (Annex III.I.4), transport (Annex III.I.5), industry (Annex III.I.6) and land-use (Annex III.I.7) models.

Modelling exercises vary considerably in terms of key characteristics, including geographical scales, time coverage, environmental variables, technologies portfolios, and socio-economic assumptions. A detailed comparison of key characteristics of global and national models used in this report is presented in Annex III.I.9. Geographical coverage ranges from sub-national (Cheng et al. 2015; Feijoo et al. 2018; Rajão et al. 2020), national (Li et al. 2019; Sugiyama et al. 2019; Vishwanathan et al. 2019; Schaeffer et al. 2020), regional (Vrontisi et al. 2016; Hanaoka and Masui 2020) and global (Gidden et al. 2018; Kriegler et al. 2018a; McCollum et al. 2018; Rogelj et al. 2019b; Drouet et al. 2021) models. Even models with the same geographical coverage can still be significantly different from each other, for instance, due to the number of regions within the model. Models can also have spatially implicit and explicit formulations, which in turn can have different spatial resolution. This distinction is especially important for land-use models, which account for changes in land use and agricultural practices (Annex III.I.7: Land-use modelling). The time horizon, time steps and time resolution are major aspects that differ across models. Model horizon can range from short- to long-term, typically reaching from a few years to up until the end of the century (Fujimori et al. 2019b; Gidden et al. 2019; Rogelj et al. 2019a; Ringkjøb et al. 2020). Time resolution is particularly relevant for specific applications, such as power sector models, which have detailed representation of power technologies dispatch and operation (Soria et al. 2016; Abujarad et al. 2017; Guan et al. 2020).

Life Cycle Assessment (LCA) is an integrated technique to evaluate the sustainability of a product throughout its life cycle. It quantifies the environmental burdens associated with all stages from the extraction of raw materials, through the production of the product

itself, its utilisation, and end-life, either via reuse, recycling or final disposal (Rebitzer et al. 2004; Finnveden et al. 2009; Guinée et al. 2011; Curran 2013; Hellweg and Milà i Canals 2014). The environmental impacts covered include all types of loads on the environment through the extraction of natural resources and emission of hazardous substances. For this reason, LCA has the flexibility to evaluate an entire product system, hence avoiding sub-optimisation in a single process and identifying the products and processes that result in the least environmental impact. Thus, it allows for the quantification of possible trade-offs between different environmental impacts (e.g., eliminating air emissions by increasing non-renewable energy resources) (Hawkins et al. 2013; Nordelöf et al. 2014; Gibon et al. 2017) and/or from one stage to other (e.g., reuse or recycling a product to bring it back in at the raw material acquisition phase) (Hertwich and Hammitt 2001a,b). It gives a holistic view of complex systems and reduces the number of parameters for which decisions have to be taken, while not glossing over technical and economical details. In recent years, LCA has been widely used in both retrospective and prospective analysis of product chains in various climate mitigation fields, namely comparing existing energy technologies with planned alternatives (Cetinkaya et al. 2012; Portugal-Pereira et al. 2015), product innovation and development (Wender et al. 2014; Portugal-Pereira et al. 2015; Sharp and Miller 2016), certification schemes (Prussi et al. 2021), or supply chain management (Hagelaar 2001; Blass and Corbett 2018).

Two different types of LCA approaches can be distinguished: Attributional Life Cycle Assessment (ALCA) and Consequential Life Cycle Assessment (CLCA). ALCA aims at describing the direct environmental impacts of a product. It typically uses average and historical data to quantify the environmental burden during a product's life cycle, and it tends to exclude market effects or other indirect effects of the production and consumption of products (Baitz 2017). CLCA, on the other hand, focuses on the effects of changes due to product life cycle, including both consequences inside and outside the product life cycle (Earles and Halog 2011). Thus, the system boundaries are generally expanded to represent direct and indirect effects of products' outputs. CLCA tends to describe more complex systems than ALCA, which are highly sensitive to data assumptions (Plevin et al. 2014; Weidema et al. 2018; Bamber et al. 2020).

Integrated assessment models (IAMs) are simplified representations of complex physical and social systems, focusing on the interaction between economy, society and the environment (Annex III.I.9). They represent the coupled energy-economy-land-climate system to varying degrees. In a way, IAMs differ among themselves on all the topics discussed in this section: significant variation in geographical, sectoral, spatial and time resolution; they rely greatly on socio-economic assumptions; different technological representation; partial or general equilibrium assumptions; differentiated between perfect foresight or recursive-dynamic methodology. The difficulty in fully representing the extent of climate damages in monetary terms may be the most important and challenging limitation of IAMs and it is mostly directed to cost-benefit IAMs. However, all categories of IAMs present important limitations (Annex III.I.9).

Following this brief synopsis of modelling taxonomies, Section I.2 details key aspects of economic frameworks and principles used to model climate mitigation responses and estimate their costs. Sections I.3, I.4, I.5, I.6, and I.7 present key aspects of sectoral modelling approaches in energy systems, buildings, transport, industry, and land use, respectively. Interactions between WGI climate emulators and WGI mitigation models are described in Section I.8. A review of integrated assessment model approaches, their components and limitations, is presented in Section I.9. Sections I.10 and I.11 present comparative tables of key characteristics and measures of national and global models that contributed to the AR6 WGI scenario database.

A.III.1.2 Economic Frameworks and Concepts Used in Sectoral Models and Integrated Assessment Models

Several types of ‘full-economy’ frameworks are used in integrated assessment models. The **general equilibrium** framework – often referred to as Computable General Equilibrium (CGE) – represents the economic interdependencies between multiple sectors and agents, and the interaction between supply and demand on multiple markets (Robinson et al. 1999). It captures the full circularity of economic flows through income and demand relationships and feedbacks including the overall balance of payments. Most CGE approaches used are neoclassical supply-led models with market clearing based on price adjustment. Representative agents usually minimise production costs or maximise utility under given production and utility function, although optimal behaviours are not a precondition *per se*. Most CGE models also include assumptions of perfect markets with full employment of factors although market imperfections and underemployment of factors (e.g., unemployment) can be assumed (Babiker and Eckaus 2007; Guivarch et al. 2011). CGE frameworks can either be static or dynamic and represent pathways as a sequence of equilibria in the second case.

Macro-econometric frameworks represent similar sectoral interdependence with balance of payments as general equilibrium, and are sometimes considered a subset of the general equilibrium framework. They differ from standard neoclassical CGE models in the main aspect that economic behaviours are not micro-founded optimising behaviours but are represented by macroeconomic and sectoral functions estimated through econometric techniques (Barker and Scricciu 2010). In addition, they usually adopt a demand-led post-Keynesian approach where final demand and investment determine supply and not the other way around. Prices also do not instantaneously clear markets and adjust with lag.

Macro-economic growth frameworks are also full-economy approaches derived from aggregated growth models. They are based on a single macroeconomic production function combining capital, labour and sometimes energy to produce a generic good for consumption and investment. They are used as the macroeconomic component of cost-benefit IAMs (Nordhaus 1993) and some detailed-process IAMs.

The **disaggregation of economic actors and sectors and the representation of their interaction** differ across full-economy frameworks. A main distinction is between models based on full Social Accounting Matrix (SAM) and aggregated growth approaches. On the one hand, SAM-based frameworks – CGE and macro-econometric – follow a multi-sectoral approach distinguishing from several to a hundred different economic sectors or production goods and represent sector-specific value-added, final consumption and interindustry intermediary consumption (Robinson 1989). They also represent economic agents (firms, households, public administration, etc.) with specific behaviours and budget constraints. On the other hand, macro-economic growth frameworks are reduced to a single macro-economic agent producing, consuming and investing a single macroeconomic good without considering interindustry relationships. In some detailed process IAMs, the aggregated growth approach is combined with a detailed representation of energy supply and demand systems that surmises different economic actors and subsectors. However, the energy system is driven by an aggregated growth engine (Bauer et al. 2008).

Partial equilibrium frameworks do not cover the full economy but only represent a subset of economic sectors and markets disconnected from the rest of the economy. They basically represent market balance and adjustments for a subset of sectors under *ceteris paribus* assumptions about other markets (labour, capital, etc.), income, and so on, ignoring possible feedbacks. Partial equilibrium frameworks are used in sectoral models, as well as to model several sectors and markets at the same time – for example, energy and agriculture markets – in energy system models and some detailed process IAMs but still without covering the full economy.

In most models the treatment of **economic growth** follows Solow or Ramsey growth approach based on the evolution through time of production factors, endowment and productivity. Classically, labour endowment and demography are exogenous, and capital accumulates through investment. Partial equilibrium frameworks do not model economic growth but use exogenous growth assumptions derived from growth models. Factors’ productivity evolution is assumed exogenous in most cases that is, general technical progress is assumed to be an autonomous process. A few models feature endogenous growth aspects where factor productivity increases with cumulated macroeconomic investment. Models also differ in the content of technical progress and alternatively consider unbiased total factor productivity improvement or labour-specific factor-augmenting productivity. In multi-sectoral macroeconomic models, economic growth comes with endogenous changes of the sectoral composition of GDP known as structural change. **Structural change** results from the interplay between differentiated changes of productivity between sectors and of the structure of final demand as income grows (Herrendorf et al. 2014). If general technical progress is mostly assumed exogenous and autonomous at an aggregated level, **innovation in relation to energy demand and technical systems** follow more detailed specifications in models. Energy efficiency can be assumed an autonomous process at different levels – macroeconomic, sector or technology – or energy technical change can be endogenous

and induced as a learning by doing process or as a result of R&D investments (learning-by-searching) (Löschel 2002).

Multi-regional models consider interactions between regions through **trade** in energy goods, non-energy goods and services – depending on model scope – and emission permits in the context of climate policy. For each type of goods, trade is usually represented as a common pool where regions interact with the pool through supply (exports) or demand (imports). A few models consider bilateral trade flows between regions. Traded goods can be assumed as perfectly substitutable between regions of origin (Heckscher-Ohlin assumption), such as is often the case for energy commodities, or as imperfectly substitutable (e.g., Armington goods) for non-energy goods. The representation of trade and capital imbalances at the regional level and their evolution through time vary across models and imbalances are either not considered (regional current accounts are balanced at each point in time), or a constraint for intertemporal balance is included (an export surplus today will be balanced by an import surplus in the future), or else trade imbalances follow other rules such as a convergence towards zero in the long run (Fouré et al. 2020).

Strategic interaction can also occur between regions, especially in the presence of externalities such as climate change, energy prices or technology spillovers. Intertemporal models can include several types of strategic interaction: (i) a cooperative Pareto optimal solution where all externalities are internalised and based on the maximisation of a global discounted welfare with weighted regional welfare (Negishi weights), (ii) a non-cooperative solution that is strategically optimal for each region (Nash equilibrium) (Leimbach et al. 2017b), and (iii) partially cooperative solutions (Eyckmans and Tulkens 2003; Yang 2008; Bréchet et al. 2011; Tulkens 2019), akin to climate clubs (Nordhaus 2015).

Models cover different **investment** flows depending on the economic framework used. Partial equilibrium models compute energy system and/or sectoral (transport, building, industry, etc.) technology-specific investment flows associated with productive capacities and equipment. Full-economy models compute both energy system and macroeconomic investment, the second being used to increase macroeconomic capital stock. Full-economy multi-sectoral models compute sector-specific (energy and non-energy sectors) investment and capital flows with some details about the investments goods involved.

Full-economy models differ in the representation of **macro-finance**. In most CGE and macro-economic growth frameworks financial mechanisms are only implicit and total financial capacity and investment are constrained by savings. Consequently, investment in a given sector (e.g., low-carbon energy) fully crowds out investment in other sectors. In macro-econometric frameworks, macro-finance is sometimes explicit, and investments can be financed by credit on top of savings, which implies more limited crowding out of investments (Mercure et al. 2019). Macro-financial constraints are usually not accounted for in partial equilibrium models.

Models compare economic flows over time through **discounting**. Table 5 summarises key characteristics of different models assessed

in AR6, including the uses of discounting. In cost-benefit analysis (CBA), discounting enables the comparison of mitigation costs and climate change damage. In the context of mitigation and in cost-effectiveness analysis (CEA), discounting allows the comparison of mitigation costs over time.

In optimisation models a social discount rate is used to compare costs and benefits over time. In the case of partial equilibrium optimisation models, the objective is typically to minimise total discounted system cost. The social discount rate is then an exogenous parameter, which can be assumed constant or changing (generally decreasing) over time (e.g., Gambhir et al. (2017), where a 5% discount rate is used). In the case of intertemporal welfare optimisation models, a Ramsey intertemporal optimisation framework is generally used, considering a representative agent who decides how to allocate her consumption, and hence saving, over time, subject to a resource constraint. Ramsey (1928) shows that the solution must always satisfy the Ramsey Equation, which provides the determinants of the social discount rate. The Ramsey Equation is given as follows:

$$\rho = \delta + \eta g_t$$

where ρ is the consumption discount rate (also known as the social discount rate), δ is the utility discount rate (also known as the pure time discount rate, or time preferences rate) which is a value judgement that determines the present value of a change in the utility experienced in the future and hence it is an ethical parameter, g_t is the growth rate of consumption per capita over time, and η is the elasticity of marginal utility of consumption, which is also a value judgement and hence an ethical parameter. The parameter η is also a measure of risk aversion and of society's aversion to inequality within and across generations. The pure time preference rate is an exogenous parameter, but the social discount rate is endogenously computed by the model itself and depends on the growth rate of consumption per capita over time. Note that more complex frameworks disentangle inequality aversion from risk aversion, and introduce uncertainty, leading to extensions of the social discount rate equation (see, for instance, Gollier 2013).

Discounting is also used for *ex post* comparison of mitigation cost pathways across models and scenarios. Values typically used for such *ex post* comparison are 2–5% (e.g., Admiraal et al. 2016). Across this report, whenever discounting is used for *ex post* comparisons, the discount rate applied is stated explicitly.

The choice of the appropriate social discount rate (and the appropriate rate of pure time preference when applicable) is highly debated (e.g., Arrow et al. 2013; Gollier and Hammitt 2014; Polasky and Dampha 2021) and two general approaches are commonly used. Based on ethical principles, the prescriptive approach states that the discount rate should reflect how costs and benefits supported by different generations should be weighted. The descriptive approach identifies the social discount rate to the risk-free rate of return to capital as observed in the real economy, which generally yields higher values.

In CBA the choice of discount rate is crucial for the balance of mitigation costs and avoided climate damages in the long run

and a lower discount rate yields more abatement effort and lower global temperature increases (Stern 2006; Hänsel et al. 2020). In CEA, the choice of social discount rate influences the timing of emission reductions to limit warming to a given temperature level. A lower discount rate increases short-term emissions reductions, lowers temperature overshoot, favours currently available mitigation options (energy efficiency, renewable energy, etc.) over future deployment of net negative emission options and distributes mitigation effort more evenly between generations (Emmerling et al. 2019; Streffler et al. 2021b).

Outside social discounting for intertemporal optimisation, discounting is used in simulation models to compute the life cycle costs of investment decisions (e.g., energy efficiency choices, choices between different types of technologies based on their levelised costs). In this case, the discount rate can be interpreted as the cost of capital faced by investors. The cost of capital influences the merit order of technologies and lower capital cost favours capital-intensive technologies over technologies with higher variable costs. Models can reflect regional, sectoral or technology-specific cost of capital – through heterogeneous discount rates for life cycle cost estimates in simulation models (Iyer et al. 2015) or as hurdle rates in energy optimisation models (Ameli et al. 2021). In some cases, simulation models may also produce mitigation pathways following the Hotelling principle and assuming that the carbon price rises at the social discount rate (e.g., Global Change Assessment Model (GCAM) scenarios in the Shared Socio-economic Pathways (SSP) study with carbon prices increasing at 5% yearly (Guivarch and Rogelj 2017)).

A.III.1.3 Energy System Modelling

In the literature, the energy system models are categorised based on different criteria, such as (i) energy sectors covered, (ii) geographical coverage, (iii) time resolution, (iv) methodology, and (v) programming techniques. In the following sections, examples on different types of energy system models applied in Chapter 6 are presented.

A.III.1.3.1 Bottom-up Models

A.III.1.3.1.1 Modelling Electricity System Operation and Planning with Large-scale Penetration of Renewables

A number of advanced grid modelling approaches have been developed (Sani Hassan et al. 2018), such as robust optimisation (Jiang et al. 2012), interval optimisation (Dvorkin et al. 2015), or stochastic optimisation (Meibom et al. 2011; Monforti et al. 2014) to optimally schedule the operation of the future low-carbon systems with high penetration of variable renewable energies. Advanced stochastic models demonstrated that this would not only lead to significantly higher cost of system management but may eventually limit the ability of the system to accommodate renewable generation (Bistline and Young 2019; Hansen et al. 2019; Perez et al. 2019; Badesa et al. 2020). Modelling tools such as *European Model for Power System Investment with Renewable Energy (EMPIRE)* (Skar et al. 2016), *Renewable Energy Mix for Sustainable Electricity Supply (REMIX)* (Scholz et al. 2017), *European Unit Commitment And*

Dispatch model (EUCAD) (Després 2015), *SWITCH* (Fripp 2012), *GenX* (TNO 2021), and *Python for Power System Analysis (PyPSA)* (Brown et al. 2018) investigated these issues. SWITCH is a stochastic model, in which investments in renewable and conventional power plants are optimised over a multi-year period (Fripp 2012). In GenX the operational flexibility as well as capacity planning is optimised from a system-wide perspective (TNO 2021). PyPSA is an optimisation model for modern electricity systems, including unit commitment of generation plants, renewable sources, storage, and interaction with other energy vectors (Brown et al. 2018).

Furthermore, advanced modelling tools have been developed for the purpose of providing estimations of system-wide inertial frequency response that would assist system operators in maintaining adequate system inertia (Sharma et al. 2011; Teng and Strbac 2017). These innovative models also provide fundamental evidence regarding the role and value of advanced technologies and control systems in supporting cost-effective operation of future electricity systems with very high penetration of renewable generation. In particular, the importance of enhancing the control capabilities of renewable generation and applying flexible technologies, such as energy storage (Hall and Bain 2008; Obi et al. 2017; Arbabzadeh et al. 2019), demand-side response, interconnection (Aghajani et al. 2017) and transmission grid extensions (Schaber et al. 2012) to provide system stability control, is demonstrated through novel system integration models (Lund et al. 2015; Sinsel et al. 2020).

A novel modelling framework is proposed to deliver inertia and support primary frequency control through variable-speed wind turbines (Morren et al. 2006) and PVs (Waffenschmidt and Hui 2016; Liu et al. 2017), including quantification of the value of this technology in future renewable generation-dominated power grids (Chu et al. 2020). Advanced models for controlling distributed energy storage systems to provide an effective virtual inertia have been developed, demonstrating the provision of virtual synchronous machine capabilities for storage devices with power electronic converters, which can support system frequency management following disturbances (Hammad et al. 2019; Markovic et al. 2019). Regarding the application of interconnection for exchange of balancing services between neighbouring power grids, alternative control schemes for high-voltage direct current (HVDC) converters have been proposed, in order to demonstrate that this would reduce the cost of balancing (Tosatto et al. 2020).

A.III.1.3.1.2 Modelling the Interaction between Different Energy Sectors

Several integrated models have been developed in order to study the interaction between different energy vectors and whole-system approaches, such as *Integrated Energy System Simulation model (IESM)* (NREL 2020), *Integrated Whole-Energy System (IWES)* (Strbac et al. 2018), *UK TIMES* (Daly and Fais 2014), and *Calliope* (Pfenninger and Pickering 2018).

IESM is an approach in which the multi-system energy challenge is investigated holistically rather than looking at each of the systems in isolation. IESM capabilities include co-optimisation across multiple

energy systems, including electricity, natural gas, hydrogen, and water systems. These provide the opportunity to perform hydro, thermal, and gas infrastructure investment and resource use coordination for time horizons ranging from sub-hourly (markets and operations) to multi-year (planning) (NREL 2020).

The IWES model incorporates detailed modelling of electricity, gas, transport, hydrogen, and heat systems and captures the complex interactions across those energy vectors. The IWES model also considers the short-term operation and long-term investment timescales (from seconds to years) simultaneously, while coordinating operation of and investment in local district and national/international level energy infrastructures (Strbac et al. 2018).

The UK TIMES Model ('The Integrated MARKAL-EFOM System') uses linear programming to produce a least-cost energy system, optimised according to a number of user constraints, over medium- to long-term time horizons. It portrays the UK energy system, from fuel extraction and trading to fuel processing and transport, electricity generation and all final energy demands (Taylor et al. 2014; Daly and Fais 2014). The model generates scenarios for the evolution of the energy system based on different assumptions around the evolution of demand and future technology costs, measuring energy system costs and all greenhouse gases (GHGs) associated with the scenario. UKTM is built using the TIMES model generator: as a partial equilibrium energy system and technologically detailed model, it is well suited to investigate the economic, social, and technological trade-offs between long-term divergent energy scenarios.

Calliope is an open source Python-based toolchain for developing energy system models, focusing on flexibility, and high temporal and spatial granularities. This model has the ability to execute many runs on the same base model, with clear separation of model (data) and framework (code) (Pfenninger and Pickering 2018).

A.III.I.3.2 Modelling of Energy Systems in the Context of the Economy

To study the impact of low-carbon energy systems on the economy, numerous integrated assessment modelling tools (top-down models) are applied, such as: *General Equilibrium Model for Economy-Energy-Environment (GEM-E3)* (Capros et al. 2013), *ENV-Linkages* (Burniaux and Chateau 2010), and *Emissions Prediction and Policy Analysis (EPPA)* (Chen et al. 2016).

GEM-E3 is a recursive dynamic computable general equilibrium model that covers the interactions between the economy, the energy system and the environment. It is specially designed to evaluate energy, climate, and environmental policies. GEM-E3 can evaluate consistently the distributional and macro-economic effects of policies for the various economic sectors and agents across the countries/regions (Capros et al. 2013).

The modelling work based on ENV-Linkages (as a successor to the OECD GREEN model) provides insights to policymakers in identifying least-cost policies by taking into account environmental issues, such

as phasing out fossil fuel subsidies, and climate change mitigation (Burniaux and Chateau 2010).

In the EPPA model, different processes (e.g., economic and technological) which have impacts on the environment from regional to global at multiple scales are simulated. The outputs of this modelling (e.g., greenhouse gas emissions, air and water pollutants) are provided to the MIT Earth System (MESM), which investigates the interaction between sub-models of physical, dynamical and chemical processes in different systems (Chen et al. 2016).

A.III.I.3.3 Hybrid Models

Hybrid models are a combination of macro-economic models (i.e., top-down) with at least one energy sector model (i.e., bottom-up) that could benefit from the advantages of both mentioned approaches. In this regard, linking these two models can be carried out either manually through transferring the data from one model to the other (soft linking), or automatically (hard linking) (Prina et al. 2020). In this section, some of these models are presented including *World Energy Model (WEM)* (IEA 2020a) and the *National Energy Modelling System (NEMS)* (Fattahi et al. 2020).

The WEM is a simulation model covering energy supply, energy transformation and energy demand. The majority of the end-use sectors use stock models to characterise the energy infrastructure. In addition, energy-related CO₂ emissions and investments related to energy developments are specified. The model is focused on determining the share of alternative technologies in satisfying energy service demand. This includes investment costs, operating and maintenance costs, fuel costs and in some cases costs for emitting CO₂ (IEA 2020a).

The NEMS is an energy-economy modelling system applied for the USA through 2030. NEMS projects consider the production, import, conversion, consumption, and prices of energy, subject to assumptions on macroeconomic and financial factors, world energy markets, resource availability and costs, behavioural and technological choice criteria, cost and performance characteristics of energy technologies, and demographics. NEMS was designed and implemented by the Energy Information Administration (EIA) of the US Department of Energy. NEMS is used by EIA to project the energy, economic, environmental, and security impacts on the United States considering alternative energy policies and assumptions related to energy markets (Fattahi et al. 2020).

A.III.I.4 Building Sector Models

A.III.I.4.1 Models: Purpose, Scope and Types

GHG emissions and mitigation potentials in the building sector are modelled using either a top-down, a bottom-up or a hybrid approach (Figure 1).

The top-down models are used for assessing economy-wide responses of building policies. These models are either economic or technological and have low granularity.

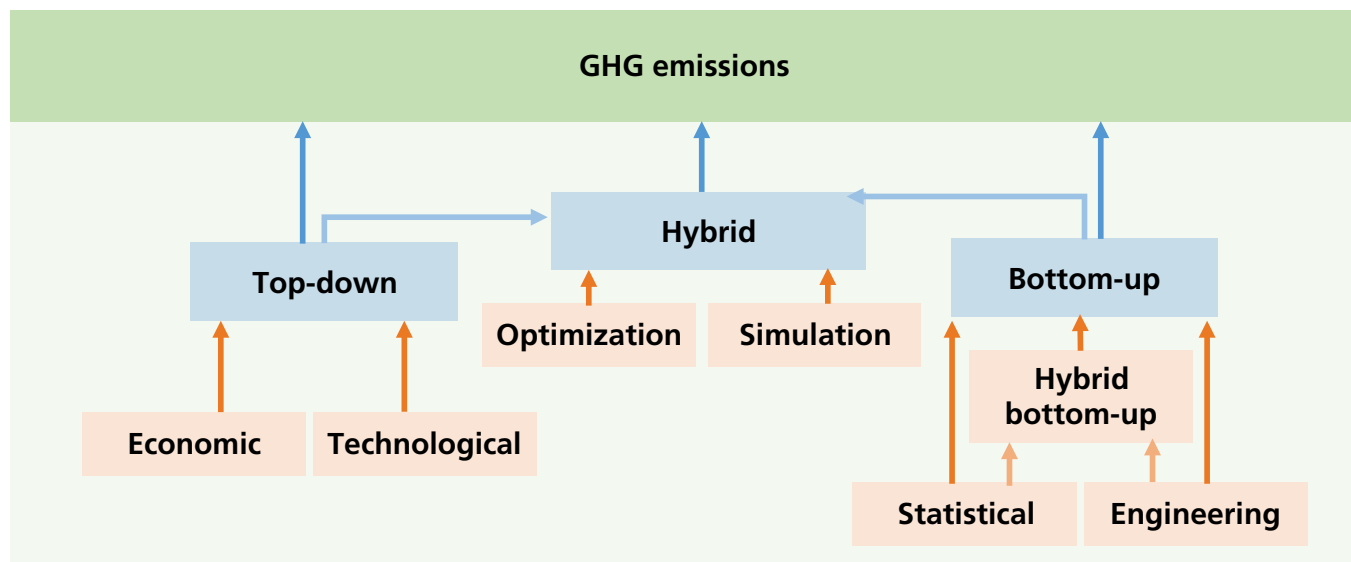

Figure 1 | Modelling approaches for GHG emissions used in the building sector.

The bottom-up models are data intensive and based on microscopic data of individual end uses and the characteristics of each component of buildings. Bottom-up models can be either physics-based, also known as engineering models; data-driven, also known as statistical models; or a combination of both, also known as hybrid bottom-up models. Bottom-up models are useful to assess the technico-economic potentials of the overall building stock by extrapolating the estimated energy consumption of a representative set of individual buildings (Duerinck et al. 2008; Hall and Buckley 2016; Bourdeau et al. 2019).

Hybrid models used for buildings can be either optimisation or simulation models (Duerinck et al. 2008; Hall and Buckley 2016; Bourdeau et al. 2019) (Figure 1). The latter can also be agent-based models and could be combined with building performance models to allow for an assessment of occupants' behaviour (Papadopoulos and Azar 2016; Sachs et al. 2019a; Niamir et al. 2020). Hybrid models are used for exploring the impacts of resource constraints and for investigating the role of specific technological choices as well as for analysing the impact of specific building policies.

The use of geographical information systems (GIS) layers (Reinhart and Cerezo Davila 2016) combined with machine learning techniques (Bourdeau et al. 2019) allows the creation of detailed datasets of building characteristics while optimising the computing time, thus, leading to a better representation of energy demand of buildings and a more accurate assessment of GHG mitigation potential.

A.III.I.4.2 Representation of Energy Demand and GHG Emissions

Comprehensive models represent energy demand per energy carrier and end use for both residential and non-residential buildings, for different countries or sets of countries, further disaggregated across urban/rural and income groups. Drivers of energy demand considered include population, the floor area per capita, appliances ownership and to some extent occupants' behaviour in residential buildings. The

former are included in top-down, hybrid and bottom-up models while the latter is usually included in bottom-up and agent-based models (Niamir et al. 2020; IEA 2021). In non-residential buildings, value added is considered among the drivers.

GHG emissions from buildings are usually modelled on the basis of the estimated energy demand per energy carrier and appropriate emissions factors. The purpose of most building models is to assess the impact of mitigation measures on energy demand in the use phase of buildings and for a given assumption on the per-capita floor area and technological improvement (IEA 2021; Pauliuk et al. 2021b). After decades of ignoring material cycles and embodied emissions (Pauliuk et al. 2017), a few IAMs are now including material stocks and flows (Deetman et al. 2020; IEA 2021; Zhong et al. 2021). However, the top-down nature of these models and the modelling methodology of embodied emissions, which are added onto the emissions estimated in the use phase, questions the policy relevance of these estimates. As of today, the resource efficiency and climate change (RECC) scenario (IRP 2020; Fishman et al. 2021; Pauliuk and Heeren 2021; Pauliuk et al. 2021b;) is the only global scenario identified which includes measures to limit, in the first place, embodied emissions from buildings. The scenario is modelled using the bottom-up ODYM-RECC model.

A.III.I.4.3 Representation of Mitigation Options

The assessment conducted in Chapter 9 was based on the SER (Sufficiency, Efficiency, Renewable), framework with sufficiency being all the measures and daily practices which avoid, in the first place, the demand for energy, materials, water, land and other natural resources over the life cycle of buildings and appliances/equipment, while providing decent living standards for all within the planetary boundaries. By contrast to efficiency, sufficiency measures do not consume energy in the use phase. Efficiency improvement of the building envelope and appliances/equipment are the main mitigation options considered in the existing models and scenarios. They are, usually, combined with market-based and information instruments and to some extent with behaviour change. As of today,

Grubler et al. (2018), Pauliuk et al. (2021b), Kuhnenn et al. (2020), Millward-Hopkins et al. (2020), Kikstra et al. (2021), and van Vuuren et al. (2021) are the only six global models/scenarios to include sufficiency measures, out of which detailed data were available only for two scenarios (Pauliuk et al. 2021b; van Vuuren et al. 2021).

In total, 931 scenarios were submitted to the AR6 scenario database, out of which only two scenarios provided detailed data allowing for an assessment of emissions reductions based on the SER framework considered in the building chapter. An additional 78 bottom-up models/scenarios were gathered (Table 1). Mitigation potentials from these scenarios are assessed using either a decomposition analysis (Section 9.3) or an aggregation of bottom-up potential estimates for different countries into regional and then global figures (Section 9.6).

Scenarios considered in the illustrative mitigation pathways included in Chapter 3 were assessed, compared to current policy scenarios. The assessment was possible for only the combined direct CO₂ emissions for both residential and non-residential buildings due to lack of data on other gases as well as on indirect and embodied emissions. The assessment shows mitigation potentials, compared to current policies scenarios, at a global level ranging from 9% to 13% by 2030 and from 58% to 89% in 2050 (Figure 2-b).

There are great discrepancies in the projected potentials by the IAMs across regions and scenarios. In the deep electrification and high renewable scenario, emissions in Africa are projected to increase by 88% by 2030, followed by a decrease of 97% by 2050, compared to current policies scenario. Similarly, in the sustainable development scenario, emissions in developing Asia are projected, compared to

current policies scenario, to increase by 56% by 2030, followed by a decrease of 75% by 2050. Such variations in emissions over two decades in the developing world raise questions about the policy relevance of these scenarios. In developed countries, emissions are projected to go down in all regions across all scenarios, except in SSP2 scenario in Asia-Pacific, where emissions are projected to increase by 18% by 2030 followed by a decrease of 25% by 2050, compared to current policies scenario. It is worth noting that, across all scenarios, Eastern Asia is the region with the lowest estimated mitigation potential compared to the current policies (Figure 2-b).

A.III.I.4.4 Representation of Sustainable Development Dimensions

The link to the Sustainable Development Goals (SDGs) is not always explicit in buildings models/scenarios. However, some models include requirements to ensure access to decent living standards for all (Grubler et al. 2018; Millward-Hopkins et al. 2020; Kikstra et al. 2021) or to specifically meet the 2030 SDG 7 goal (IEA 2020a, 2021).

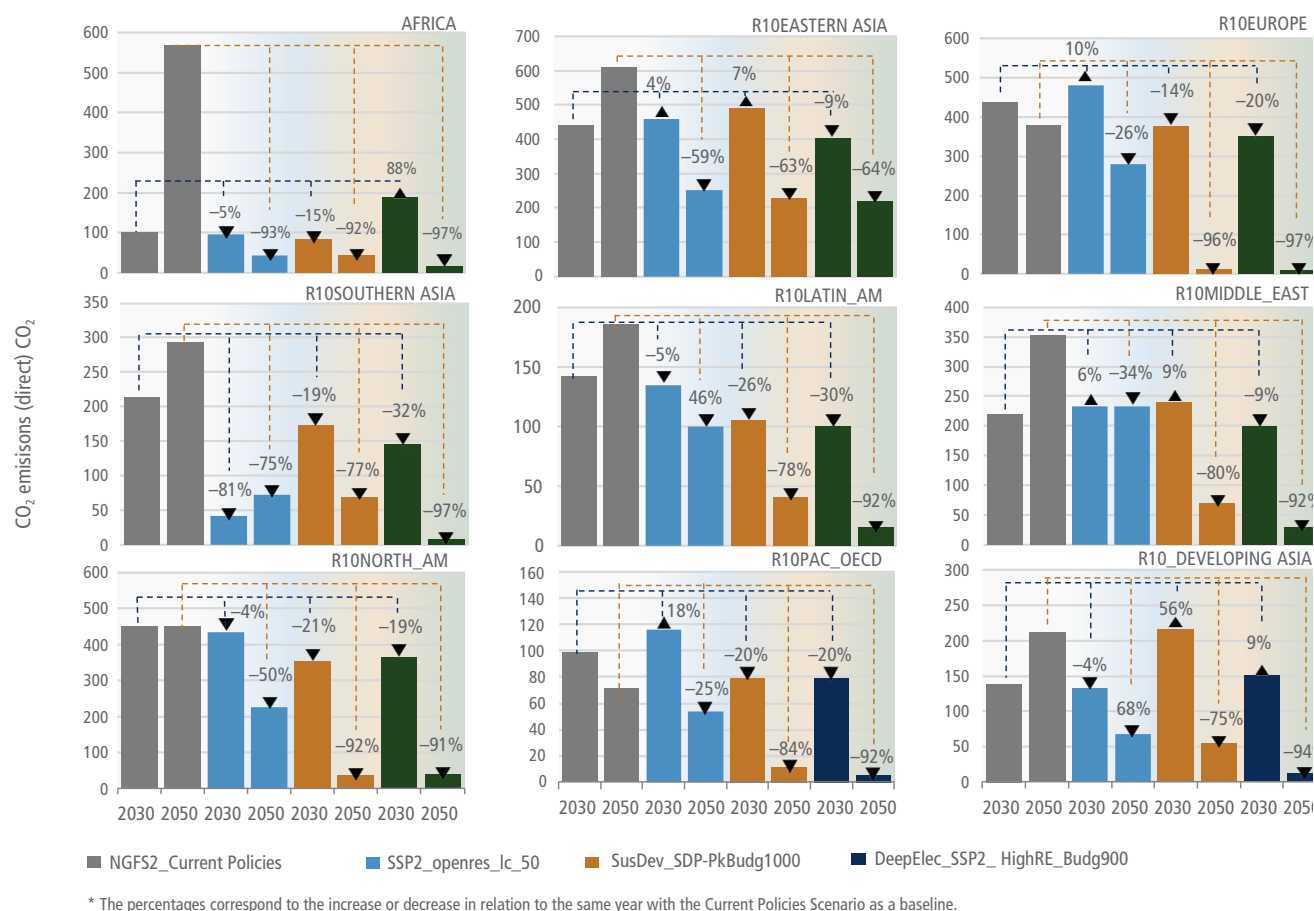

A.III.I.4.5 Models Underlying the Assessment in Chapter 9

The AR6 scenario database received 101 models with a building component, out of which 96 were IAM models and five building specific models. This is equivalent to 931 scenarios. After an initial screening, quality control and further vetting to assess if they sufficiently represented historical trends and climate goals, 43 models (42 IAMs and 1 building-specific model) were kept for the assessment, thus reducing the number of scenarios to assess to 554. The unvetted scenarios are still available in the database.

a) Global

Figure 2 | GHG emissions reductions in the building sector (direct emissions) in scenarios considered as illustrative mitigation pathways in Chapter 3.

b) Regional

Figure 2 (continued): GHG mitigation potentials of scenarios considered in the illustrative mitigation pathways considered in Chapter 3.

After a final screening based on the SER (Sufficiency, Efficiency, Renewable) framework, only two IAMs were kept. Given the top-down nature of IAMs and their weaknesses in assessing mitigation measures, especially sufficiency measures, 78 bottom-up models with technological representation have been included in the assessment (Table 1). These additional bottom-up models were not submitted to the AR6 scenario database. However, scenario owners supplied Chapter 9 with the underlying assumptions and data.

A.III.I.5 Transport Models

A.III.I.5.1 Purpose and Scope of Models

GHG emissions from transport are largely a function of **travel demand**, **transport mode**, and **transport technology and fuel**. The purpose of transportation system models is to describe how future **demand** for transport can be fulfilled through different **modes** and **technologies** under different climate change mitigation targets or policies. Within a given transport mode, technologies differ by efficiency and fuel use.

Common components of transportation energy systems models mirror these main drivers of GHG emissions. Most models will also quantify

how much movement occurs, or the **travel demand** associated with each mode. Models commonly quantify demand through **transportation mode** (e.g., active transit, passenger vehicles, trucks, boats, planes, etc.) or how movement occurs (e.g., passenger travel distance pkm and freight distance tkm). Higher fidelity models provide more nuanced breakdowns of demand by trips of various lengths such as short-, medium-, and long-distance trips or by region (e.g., kilometres or tkm per region). The scope of the model often determines how much information it provides on where and when movement occurs. While larger scale models typically provide aggregate travel demand, higher resolution travel demand models can be integrated into transportation system models and provide much more information on origin and destination of trips, when and where trips occur, and the route of travel taken. This level of detail is not often characterised in the output of system models but can be employed as a 'base' model to determine how travel occurs before aggregation (Edelenbosch et al. 2017a; Yeh et al. 2017).

A key distinguishing feature between different model types is how they control the above components. Our review of the transport energy system models can be broadly divided into three main categories: (i) optimisation models, (ii) simulation models, and (iii) accounting and exploratory models.

Table 1 | Models underlying the assessment in Chapter 9.

Model name/ institution using the model	Model description	Geographic scope	Building type included	Energy demand	Example of publications
World Energy Model (WEM)/International Energy Agency (IEA)	A simulation model with detailed bottom-up building stock model	Global	Residential and non-residential	The building module includes a stock model with detailed technologies, end uses and energy carriers. Activity variables such as floor area and appliance ownership are projected by end use. A cost-based approach, influenced by policy and other constraints, is used to allocate between almost 100 technologies. Energy demand projections are based on country-level historical data for both residential and non-residential buildings. The buildings module is integrated within the wider World Energy Model.	IEA (2020a); IEA (2021)
IMAGE 3.2 model/ Netherlands Environmental Assessment Agency	A modular integrated assessment model using a simulation model for energy demand	Global	Residential and non-residential buildings	Energy demand is calculated as a function of household expenditure and population growth, disaggregating across urban/rural and income groups. The model includes a building stock model (residential) with a detailed description of end uses, energy carrier use and building technologies for both residential and non-residential buildings. A scenario analysis assessing assumptions on lifestyle changes has also been conducted.	van Vuuren et al. (2021)
Resource Efficiency and Climate Change (RECC) model. Research Institutions: Norwegian University of Science & Technology and University of Freiburg. Funding Institutions: UNEP and International Resource Panel	Bottom-up building stock-flow model estimating material and energy flows associated with housing stock growth, driven by input parameters of population and floor area per capita	Global	Residential buildings	Energy demand is calculated the model BuildME, a physical model using the EnergyPlus simulation engine, incorporating country/region-specific projections of envelope and equipment efficiency.	IRP (2020); Fishman et al. (2021); Pauliuk and Heeren (2021); Pauliuk et al. (2021a); Pauliuk et al. (2021b)
A total of 77 bottom-up models out of which 67 were technology-rich and 10 sufficiency-focused	Bottom-up technology-rich models with detailed building and other technology stock models	Three global (all sufficiency models), six regional (regions here refer to regions including several countries), two subnational, and the rest national	Residential and/or non-residential buildings	In most cases, energy demand was modelled by multiplying units of energy consumption of technologies/product/buildings by stocks of corresponding technologies/products and/or buildings at national level. The projected stocks of buildings and/or technologies/products are modelled based on past levels. The potential is demonstrated by replacing the business-as-usual technologies and practices with demonstrated best available or commercially feasible technologies and practices. The studies rely on some or all of the following mitigation options: the construction of new high-performance buildings using building design, forms, and passive construction methods; the thermal efficiency improvement of building envelopes of the existing stock; the installation of advanced heating, ventilation air conditioning systems, equipment and appliances; the exchange of lights, appliances, and office equipment, including ICT, water heating, and cooking; active and passive demand-side management measures; as well as on-site production and use of renewable energy. Many bottom-up studies considered the measures as an integrated package due to their technological complementarity and interdependence, rather than the penetration of individual technologies applied in an incremental manner in or to these buildings. - i. **Optimisation models:** Identify least cost pathways to meet policy targets (such as CO₂ emission targets of transport modes or economy-wide) given constraints (such as rate of adoption of vehicle technologies or vehicle efficiency standards). For example MessagelX-TransportV5 (Krey et al. 2016) and TIMES (Daly et al. 2014).
- ii. **Simulation models:** Simulate behaviour of consumers and producers given prices, policies, and other factors by using parameters calibrated to historically observed behaviours such as demand price elasticity and consumer preferences. For example models by Barter et al. (2015), Brooker et al. (2015) and Schäfer (2017).
- iii. **Accounting and exploratory models:** Track the outcomes (such as resources use and emissions) of key decisions (such as the adoption of advanced fuels or vehicle technologies) that are based on 'what-if' scenarios. The major difference between accounting models versus optimisation and simulation models is that key decision variables such as new technologies adoptions typically follow modellers' assumptions as opposed to being determined by mathematical formulations as in optimisation and simulation models. See models in Fulton et al. (2009), IEA (2020a), Gota et al. (2019) and Khalili et al. (2019).

Due to the model types' relative strengths and weaknesses, they are commonly applied to certain problem types (Table 2). Models can do **forecasting**, which makes projections of how futures may evolve, or **backcasting**, which makes projections of a future that meets a predefined goal such as a policy target of 80% reduction in GHG emissions from a historical level by a certain year. Models are often also used to explore 'what-if' questions, to confirm the **feasibility** of certain assumptions/outcomes, and to quantify the **impacts** of a change such as a policy under different conditions. Enhancing fuel efficiency standards, banning internal combustion engines, setting fuel quality standards, and the impacts of new technologies are typical examples of problem types analysed in energy system models.

While these four model types drive the component dynamics in different ways, they commonly include modules that include: learning and diffusion (via exogenous, e.g., autonomous learning, or endogenous learning regarding costs and efficiency: i.e., cost decreases and/or efficiency increases as a function of adoption, and increased diffusion due to lower costs) (Jochem et al. 2018), stock turnover (the performance and characteristics of vehicle fleets including survival ages, mileages, fuel economies and loads/occupancy rates are tracked for each new sales/vehicle stocks), consumer choice (theories of how people invest in new technology and utilise different modes of transport based on their individual

preferences given the characteristics of mode or technology) (Daly et al. 2014; Schäfer 2017), or other feedback loops (Linton et al. 2015).

IAMs (Krey et al. 2016; Edelenbosch et al. 2017a) are typically global in scope and seek to solve for feasible pathways meeting a global temperature target (Annex III.I.9). This implies finding least-cost mitigation options within and across sectors. In contrast, global and national transport energy system models (GTEMs/NTEMs) typically only assess feasible pathways within the transport sector (Yeh et al. 2017). The range of feasible pathways can be determined through optimisation, simulation, accounting and exploratory methods, as outlined in Table 2. Some GTEMs are linked to an IAMs model (Krey et al. 2016; Edelenbosch et al. 2017a; Roelfsema et al. 2020). The key difference between IAMs and GTEMs or NTEMs is whether the transportation system is integrated with the rest of the energy systems, specifically regarding energy and fuel production and use, fuel prices, economic drivers such as GDP, and mitigation options given a policy goal. IAMs can endogenously determine these factors because the transport sector is just one of many sectors captured by the IAM. While this gives IAMs certain advantages, IAMs sacrifice resolution and complexity for this broader scope. For example, most IAMs lack a sophisticated travel demand model that reflects the heterogeneity of demands and consumer preferences, whereas GTEM/NTEMs can incorporate greater levels of details regarding travel demands, consumer choices, and the details of transport policies. Consequently, what GTEMs/NTEMs lack in integration with other sectors they make up through more detailed analyses of travel patterns, policies, and impacts (Yeh et al. 2017).

Several noteworthy recent active research areas in long-term transportation energy systems modelling involves the consideration of infrastructure investment and consumer acceptance for non-fossil fuel vehicles including charging for electric vehicles (Jochem et al. 2019; Statharas et al. 2021) and refuelling stations for hydrogen vehicles (Rose and Neumann 2020); and the greater integration of the electric, transport, residential, and industrial sectors in fuel production, storage, and utilisation (Bellocchi et al. 2020; Lester et al. 2020; Olovsson et al. 2021; Rottoli et al. 2021). While national and regional transport energy models have the advantage of exploring these relationships in greater spatial, temporal, and policy details for specific countries or regions (Jochem et al. 2019; Bellocchi et al. 2020; Lester et al. 2020; Rottoli et al. 2021; Statharas et al. 2021), the IAMs have the advantage of examining these interactions across the entire economy at the global level (Brear et al. 2020; Rottoli et al. 2021).

Table 3 | GTEM/NTEMs models evaluated in Chapter 10.

Model name	Organisation	Scope	Resolution	Period	Economy-wide	Method
Mobility model (MoMo)	International Energy Agency (IEA)	Global	Country groups	2050	Soft link	Accounting model
Global Transportation Roadmap	International Council on Clean Transportation (ICCT)	Global	Country groups	2050	No	Accounting model
MESSAGE-Transport V.5	International Institute for Applied Systems Analysis (IIASA)	Global	Country groups	2100	Yes	Optimisation model
Global Change Assessment Model (GCAM)	Pacific Northwest National Laboratory (PNNL)	Global	Country groups	2100	Yes	Partial equilibrium model

The global/national transport energy system models included in the transportation chapter (Chapter 10) are listed below in Table 3.

A.III.1.6 Industry Sector Models

A.III.1.6.1 Types of Industry Sector Models

Industry sector modelling approaches can vary considerably from one another. As with other types of models, a key characteristic of industry sector models is related to their geographical scope. While IAMs are often global in scope, many bottom-up sector models are limited to individual countries or regions. The models' system boundaries also differ, with some models fully considering the use of energy for feedstock purposes and other models focusing only on the use of energy for energetic purposes. Differences between models also exist in regard to differentiation between the industry sector and the energy transformation sector, concerning, for example, refineries and industrial power plants.

A.III.1.6.2 Representation of Demand for Industrial Products

Industry sector models vary in regard to their representation of demand for industrial goods or products. A more detailed representation of demand in a model allows for a more explicit discussion of different types of drivers of industrial demand and therefore a more detailed

representation of demand-side strategies such as material recycling, longer use of products or sharing of products.

Particularly, demand for industrial products is often considered in more detail in bottom-up models of the industry sector than in top-down models by taking more drivers into account. These drivers can be, inter alia, population, gross value added, construction activity, transport activity, but also changes in material efficiency, recycling rates and scrap rates as well as product use efficiency (e.g., through longer use of products or sharing of products) (Fleiter et al. 2018; Material Economics 2019; IEA 2020b).

A.III.1.6.3 Representation of Mitigation Options

In most top-down IAMs, some energy-intensive sectors, such as iron and steel or cement, are included separately, at least in a generalised manner, but typically few if any sector-specific technologies are explicitly represented. Instead, energy efficiency improvements in the industry sector and its subsectors are often either determined by exogenous assumptions or are a function of energy prices. Likewise, fuel switching occurs primarily as a result of changes in relative fuel prices, which in turn are influenced by CO₂ price developments. In IAMs that include specific technologies, fuel switching can be constrained based on the characteristics of those technologies, while in IAMs with no technological detail, more generic

Table 4 | Models underlying specific assessments in Chapter 11.

Model name and institution using the model	Model description	Geo-graphic scope	Industrial sectors included/ distinguished	Demand for industrial products	Examples of publications
Industry sector model of the Energy Technology Perspectives model (IEA)	The bottom-up industry sector model is one of four soft-linked models making up the ETP model. The four models are an energy supply optimisation model and three end-use sector models (transport, industry, buildings). Technologies and fuels in the industry sector model are chosen based on cost optimisation.	Global	Aluminium, iron and steel, chemical and petrochemical, cement, pulp and paper and other industry sectors	Demand for industrial products is derived based on country-level historical data on per capita consumption. This per capita consumption is projected forward by using population projections and industry value-added projections. Demand for materials is derived by also taking the build-up of material stocks into account.	IEA (2020b, 2021)
World Energy Model (IEA)	Simulation model consisting inter alia of technologically detailed bottom-up representations of several industry sectors	Global	See ETP model	See ETP model	IEA (2020a, 2021)
Material Economics modelling framework	Modelling tool consisting of several separate bottom-up models	European Union	Steel, chemicals (plastics and ammonia), cement	Demand for industrial products is derived based on scenarios of future activity levels in key segments such as construction, mobility and food production. Separate models additionally explore opportunities for improving materials efficiency and increasing materials circulation.	Material Economics (2019)

constraints on fuel switching in the industry sector are embedded (Edelenbosch et al. 2017b).

In bottom-up models, individual technological mitigation options are represented in detail, especially for energy-intensive sectors such as iron and steel, cement and chemicals. Typically, for each considered technology, not only specific energy demand but also investment and operating costs are included in these models. Investment costs can change over time, either based on an exogenous assumption or on an endogenised process such as a learning rate. While bottom-up models often consider technology-specific learning, IAMs cover technological progress in a more general way associated to industry branches. The uptake of new technologies is typically restricted in bottom-up models, for example by assuming a minimum lifetime for existing stock or by assuming S-shaped diffusion curves (Fleiter et al. 2018). The industrial sector models included in the industry chapter (Chapter 11) are listed in Table 4.

A.III.1.6.4 Limitations and Critical Analysis

Aggregated, top-down models of the industry sector, as used in most IAMs, are typically calibrated based on long-term historical data, for example on the diffusion of new technologies or on new fuels. These models are therefore able to implicitly consider real-life restrictions of the whole sector that bottom-up models (with their focus on individual technologies) may not fully take into account. These restrictions may arise, inter alia, from delays in the construction of infrastructure or market actors possessing incomplete information about new technologies. Furthermore, as IAMs also model the climate system, these models can principally take into account potential repercussions of climate change impacts on the growth rate and structure of economies.

However, a downside of top-down models is that they are typically limited in their representation of individual technologies and processes in the industry sector and particularly of technology-driven structural change. This lack of technological detail limits the usefulness of these models to analyse technology-specific and sector-specific mitigation measures and related policies. Top-down models also tend to have a relatively aggregated representation of industrial energy demand, meaning demand-side mitigations strategies such as recycling, product-service efficiency and demand reduction options are difficult to assess with these models (Pauliuk et al. 2017).

In contrast, technology-rich bottom-up models allow detailed analysis of the potential of new technologies, processes and fuels in individual industrial sectors to reduce GHG emissions. Their often-detailed analysis of the demand side allows demand-side mitigation strategies to be evaluated. Furthermore, radical future changes in technology, climate policy or social norms can more easily be reflected in bottom-up models than in top-down models which are calibrated on past observations. Both types of models are typically not able to account for product substitution (e.g., steel vs plastics) arising from changing production cost differentials or changing product quality due to new production processes. In principle, technology-rich input-output models could fill this gap.

A.III.1.7 Land-use Modelling

Land use related IAM modelling results as presented in Chapter 7 are based on comprehensive land-use models (LUMs) that are either integrated directly, or through emulators, into the integrated assessment framework. Given the increasing awareness of the importance of the land use sector to achieve ambitious climate mitigation targets, LUMs and their integration into IAM systems was one of the key innovations to the integrated assessment over the past decade to allow for an economy-wide quantification of climate stabilisation pathways.

LUMs allow developments in the land-use sector to be projected over time and the impacts of mitigation policies on different economic (markets, trade, prices, demand, supply, etc.) and environmental (land use, emissions, fertiliser, irrigation water use, etc.) indicators to be assessed. The following models submitted scenarios to the AR6 database: AIM (Fujimori et al. 2014, 2017; Hasegawa et al. 2017), EPPA (Chen et al. 2016), GCAM (Calvin et al. 2019), IMAGE (Stehfest et al. 2014), MERGE, MESSAGE-GLOBIOM (Havlik et al. 2014; Fricko et al. 2017; Huppmann et al. 2019), POLES (Keramidas et al. 2017), REMIND-MAGPIE (Kriegler et al. 2017; Dietrich et al. 2019), WITCH (Emmerling et al. 2016).

A.III.1.7.1 Modelling of Land Use and Land-use Change

LUMs represent different land use activities for managed land (agriculture including cropland and pastures, managed forests, and dedicated energy crops) while natural lands (primary forests, natural grasslands, shrubland, savannahs, etc.) act as land reserves that can be converted to management depending on other constraints (Popp et al. 2014a; Schmitz et al. 2014). Typically, the agricultural sector has the greatest level of detail across land use sectors. LUMs include different crop and livestock production activities, some even at the spatially explicit level and differentiated by production system (Havlik et al. 2014; Weindl et al. 2015). Forestry is covered with varying degrees of complexity across LUMs. While some models represent only afforestation/deforestation activities dynamically, others have detailed representation of forest management activities and/or forest industries (Lauri et al. 2017). The models endogenously determine the land allocation of different land use activities as well as land-use changes according to different economic principles (land rent, substitution elasticities, etc.) and/or considering biophysical characteristics such as land suitability (Schmitz et al. 2014; Weindl et al. 2017).

A.III.1.7.2 Demand for Food, Feed, Fibre and Agricultural Trade

LUMs project demand for food, feed, other industrial or energy uses for different agriculture and forestry commodities over time. While partial equilibrium models typically use reduced-form demand functions with greater level of detail at the commodity level, however limited agriculture and forestry, Computable General Equilibrium (CGE) models represent demand starting from utility functions from which it is possible to derive demand functions, and functional forms for income and price elasticities, however for a more limited set of agricultural and forestry commodities but with full coverage of all economic sectors (Valin et al. 2014; von Lampe et al. 2014). Over

time, demand for food, feed, and other industrial uses is projected conditional on population and income growth while bioenergy demand is typically informed in partial equilibrium (PE) models by linking with IAMs/energy systems models, and is usually endogenous in CGE/IAMs (Hasegawa et al. 2020). Depending on the model, demand projections are sensitive to price changes (Valin et al. 2014). International trade is often represented in LUMs using either Armington or spatial equilibrium approaches (von Lampe et al. 2014).

A.III.1.7.3 Treatment of Land-based Mitigation Options

Two broad categories of land-based mitigation options are represented in LUMs: (i) reduction of GHG (CO₂, CH₄ and N₂O) emissions from land use, and (ii) carbon sink enhancement options including biomass supply for bioenergy. Each of these categories is underpinned by a portfolio of mitigation options with varying degrees of complexity and parameterisation across LUMs. The representation of mitigation measures is influenced on the one hand by the availability of data for its techno-economic characteristics and future prospects as well as the computational challenge, for example in terms of spatial and process detail, to represent the measure, and on the other hand, by structural differences and general focus of the different LUMs, and prioritisation of different mitigation options by the modelling teams. While GHG emission reduction and CO₂ sequestration options such as afforestation are typically covered directly in LUMs (Hasegawa et al. 2021), carbon sequestration from biomass supplied for bioenergy with carbon capture and storage (BECCS) is usually not accounted for in LUMs but in the energy sector and hence is taken care of directly in the IAMs. Yet, LUMs provide estimates of available biomass for energy production and the impacts of its production.

A.III.1.7.3.1 Treatment of GHG Emissions Reduction

Agricultural non-CO₂ emissions covered in LUMs include CH₄ from enteric fermentation, manure management and cultivation of rice paddies, and N₂O emissions from soils (fertiliser and manure application, crop residues) and manure management and are based on IPCC accounting guidelines (IPCC 2019a). For each of those sources, LUMs typically represent a (sub)set of technical, structural and demand-side mitigation options. Technical options refer to technologies such as anaerobic digesters, feed supplements or nitrogen inhibitors that are either explicitly represented (Frank et al. 2018) or implicitly via the use of marginal abatement cost curves (MACC) (Lucas et al. 2007; Beach et al. 2015; Harmsen et al. 2019). Emission savings from structural changes refer to more fundamental changes in the agricultural sector, for example through international trade, production system changes or reallocation and substitution effects (Havlik et al. 2014). Demand-side options include dietary changes and reduction of food waste (Springmann et al. 2016; Creutzig et al. 2018; Ritchie et al. 2018; Frank et al. 2019; Mbow et al. 2019; Clark et al. 2020; Ivanova et al. 2020; Popp et al. 2010; Rosenzweig et al. 2020). For the forest sector, emission reduction options are mainly targeting CO₂ from deforestation (Overmars et al. 2014; Hasegawa et al. 2017; Rochedo et al. 2018; Bos et al. 2020; Doelman et al. 2020; Eriksson 2020). Mitigation/restoration options for wetlands to reduce emissions from drained organic soils are typically not represented in LUMs (Humpenöder et al. 2020).

There are significant differences between UNFCCC nationally reported GHG inventories and analytical global land use models. According to Grassi et al. (2017), this discrepancy results in a 3GtCO₂-eq difference in estimates between country reports and global models. The difference relies on different methods to classify and assess managed forests and forest management fluxes (Houghton et al. 2012; Pongratz et al. 2014; Smith et al. 2014; Tubiello et al. 2015; Grassi et al. 2017, 2021). While global models account for GHG emissions from indirect human-induced effects and natural effects in unmanaged land, countries only consider fluxes of land use and land-use change in managed land. In order to produce policy-relevant land-use model exercises, reconciling these differences is needed by harmonising definitions and approaches of anthropogenic land and the treatment of indirect environmental change (Grassi et al. 2017).

A.III.1.7.3.2 Treatment of Terrestrial Carbon Dioxide Removal Options including Biomass Supply for Bioenergy

Terrestrial carbon dioxide removal options are only partially included in LUMs and mostly rely on afforestation and bioenergy with carbon capture and storage (BECCS) (Fuss et al. 2014, 2018; Minx et al. 2018; Smith et al. 2019; Butnar et al. 2020). Especially some nature-based solutions (Griscom et al. 2017) such as soil carbon management (Paustian et al. 2016), which have the potential to alter the contribution of land-based mitigation in terms of timing, potential and sustainability consequences, are only recently being implemented in LUMs (Frank et al. 2017; Humpenöder et al. 2020). The representation of bioenergy feedstocks varies across models but typically LUMs have comprehensive representation of a series of crops (starch, sugar, oil, wood/lignocellulosic feedstocks) or residues/byproducts that can be used for liquid and solid bioenergy production (Hanssen et al. 2019).

A.III.1.7.4 Treatment of Environmental and Socio-economic Impacts of Land Use

Aside reporting the implications on agriculture, forestry and other land use (AFOLU) GHG emissions, LUMs can provide a set of environmental and socio-economic impact indicators to assess the quantified climate stabilisation pathways in a broader sustainable development agenda (van Vuuren et al. 2015; Obersteiner et al. 2016; van Vuuren et al. 2019; Frank et al. 2021; Soergel et al. 2021). These indicators typically span from land use area developments (Popp et al. 2017; Stehfest et al. 2019), fertiliser use, irrigation water use and environmental flows (Bonsch et al. 2015; Pastor et al. 2019; Chang et al. 2021; de Vos et al. 2021), and on biodiversity (Leclère et al. 2020; Marquardt et al. 2021), to market impacts on commodity prices and food consumption, or impact on undernourishment (Hasegawa et al. 2018; Doelman et al. 2019; Fujimori et al. 2019a; Hasegawa et al. 2020; Soergel et al. 2021).

A.III.1.8 Reduced Complexity Climate Modelling

Climate model emulators (often referred to as reduced complexity or simple climate models) are used to integrate the WGI knowledge of physical climate science into the WGIII assessment. Hence, emulators are used to assess the climate implications of the GHG and other

emissions trajectories that IAMs produce (van Vuuren et al. 2008; Rogelj et al. 2011; Clarke et al. 2014; Schaeffer et al. 2015; Rogelj et al. 2018a). The IAM literature typically uses one of two approaches: comprehensive emulators such as MAGICC (Meinshausen et al. 2011) or Hector (Hartin et al. 2015) or minimal complexity representations such as the representation used in DICE (Nordhaus 2018), PAGE (Yumashev et al. 2019; Kikstra et al. 2021c) and Fund (Waldhoff et al. 2014). In physical science research, a wider range of different emulators are used (Nicholls et al. 2020b, 2021a).

A key application of emulators within IPCC WGIII is the classification of emission scenarios with respect to their global mean temperature outcomes (Clarke et al. 2014; Rogelj et al. 2018a). WGIII relies on emulators to assess the full range of carbon-cycle and climate response uncertainty of thousands of scenarios, as assessed by AR6 WGI. An exercise of such amplitude is currently infeasible with more computationally demanding state-of-the-art Earth system models. Cross-Chapter Box 7.1 in AR6 WGI documents how emulators used in WGIII are consistent with the physical science assessment of WGI (Forster et al. 2021).

Previous IPCC Assessment Reports relied either on the climate output from each individual IAM (IPCC 2000) or a more streamlined approach, where one consistent emulator set-up was used to assess all scenarios. For instance, in AR5 and the Special Report on Global Warming of 1.5°C (SR1.5), MAGICC was used for scenario classification (Clarke et al. 2014; Rogelj et al. 2018a). In recent years, numerous other emulators have been developed and increased confidence and understanding can thus be gained by combining insights from more than one emulator. For example, SR1.5 used MAGICC for its scenario classification, with additional insights provided by the FaIR model (Smith et al. 2018). The SR1.5 experience highlighted that the veracity of emulators ‘is a substantial knowledge gap in the overall assessment of pathways and their temperature thresholds’ (Rogelj et al. 2018a). Since SR1.5, international research efforts have demonstrated tractable ways to compare emulator performance (Nicholls et al. 2020b), as well as their ability to accurately represent a set of uncertainty ranges in physical parameters (Nicholls et al. 2021b), such as those reported by AR6 WGI (Forster et al. 2021).

Finally, the recently developed OpenSCM-Runner package (Nicholls et al. 2020a) provides users with the ability to run multiple emulators from a single interface. OpenSCM-Runner has been built in collaboration with the WGIII research community and forms part of the WGIII assessment (Annex III.II.2.5.1).

A.III.I.9 Integrated Assessment Modelling

Process-based integrated assessment models (IAMs) describe the coupled energy-land-economy-climate system (Weyant 2009; Krey 2014; Weyant 2017). They typically capture all greenhouse gas (GHG) emissions induced by human activities and, in many cases, emissions of other climate forcers like sulphate aerosols. Process-based IAMs represent most GHG and climate pollutant emissions by modelling the underlying processes in energy and land use. Those models are able to endogenously describe the change in emissions due to changes in energy and land use activities, particularly in response to climate action. But IAMs differ in the extent to which all emissions and the corresponding sources, processes and activities are represented endogenously and, thus, can be subjected to policy analysis.¹ IAMs also differ regarding the scope of representing carbon removal options and their interlinkage with other vital systems such as the energy and land-use sectors.

Typically, IAMs consider multi-level systems of global, regional, national and local constraints and balance equations for different categories such as emissions, material and energy flows, financial flows, and land availability that are solved simultaneously. Intertemporal IAMs can fully incorporate not only flow constraints that are satisfied in each period, but also stock constraints that are aggregated over time and require to balance activities over time. Changes of activities, for example induced by policies to reduce emissions, are connected to a variety of balance equations and constraints and therefore such policies lead to system-wide changes that can be analysed with IAMs. Many IAMs also contain gridded components to capture, for example, land-use and climate change processes where the spatial distribution matters greatly for the dynamics of the system. Processes that operate on smaller spatial and temporal scales than resolved by IAMs, such as temporal variability of renewables, are included by parameterisation and statistical modelling approaches that capture the impact of these subscale processes on the system dynamics at the macro level (Pietzcker et al. 2017).

Global IAMs are used to analyse global emissions scenarios extrapolating current trends under a variety of assumptions and climate change action pathways under a variety of global goals. In recent years, a class of national and regional IAMs have emerged that describe the coupled energy-land-economy system in a given geography. They typically have higher sectoral, policy and technology resolution than global models and make assumptions about boundary conditions set by global markets and international policy regimes. These IAMs are used to study trends and transformation pathways for a given region (Shukla and Chaturvedi 2011; Capros et al. 2014; Lucena et al. 2016).

¹ See the common IAM documentation at www.iamcdocumentation.eu.

A.III.1.9.1 Types of Integrated Assessment Models

IAMs include a variety of model types that can be distinguished into two broad classes (Weyant 2017). The first class comprises *cost-benefit IAMs* that fully integrate a stylised socio-economic model with a reduced-form climate model to simultaneously account for the costs of mitigation and the damages of global warming using highly aggregate cost functions derived from more detailed models. In the model context, these functions do not explicitly represent the underlying processes, but map mitigation efforts and temperature to costs. This closed-loop approach between climate and socio-economic systems enables cost-benefit analysis by balancing the cost of mitigation and the benefits of avoided climate damages. This can be done in a globally cooperative setting to derive the globally optimal climate policy where no region can further improve its welfare without reducing the welfare of another region (Pareto optimum). Alternatively, it can be assumed that nations do not engage in emission mitigation at all or mitigate in a non-cooperative way, only considering the marginal benefit of their own action (Nash equilibrium). Also, differing degrees of partial cooperation are possible.

The second class of IAMs, called *process-based IAMs*, focuses on the analysis of transformation processes depending on a broad set of activities that induce emissions as side effects. They describe the interlinkages between economic activity, energy use, land use, and emissions with emission reductions and removals as well as broader sustainable development targets. GHGs and other climate pollutants are caused by a broad range of activities that are driven by socio-economic developments (Riahi et al. 2017) and also induce broader environmental consequences such as land-use change (Popp et al. 2017) and air pollution (Rao et al. 2017b). With few exceptions, these models typically do not close the loop with climate change and damages that affect the economy, but focus on emission scenarios and climate change mitigation pathways. Due to the process-based representations of emission sources and alternatives, it is not only possible to investigate the implications of policies on GHG emissions, but also the trade-offs and synergies with social and environmental sustainability criteria (von Stechow et al. 2015) (Annex III.1.9.3). The analysis of different cross-sectoral synergies and trade-offs is frequently termed a *nexus analysis*, such as the energy-water-land nexus. The analysis can also address socio-economic sustainability criteria such as energy access and human health. Process-based IAMs are also used to explore the synergies and trade-offs of 'common, but differentiated responsibilities' by analysing issues of burden sharing, equity, international cooperation, policy differentiation and transfer measures (Tavoni et al. 2015; Fujimori et al. 2016; Leimbach and Giannousakis 2019; Bauer et al. 2020b).

There exists a broad range of process-based IAMs that differ regarding the economic modelling approaches (Annex III.1.2) as well as the methodology and detail of sector representation (Annex III.1.3–7) and how they are interlinked with each other.

This leads to differences in model results regarding global aggregates as well as sectoral and regional outputs. Several approaches have been used to evaluate the performance of IAMs and understand differences in IAM behaviour (Schwanitz 2013; Wilson et al. 2021),

including sensitivity analysis (McJeon et al. 2011; Luderer et al. 2013; Rogelj et al. 2013a; Bosetti et al. 2015; Marangoni et al. 2017; Giannousakis et al. 2021), model comparisons (Clarke et al. 2009; Kriegler et al. 2014a, 2015a; Riahi et al. 2015; Tavoni et al. 2015; Kriegler et al. 2016; Riahi et al. 2017; Luderer et al. 2018; Roelfsema et al. 2020; Riahi et al. 2021; van Soest et al. 2021), model diagnostics (Kriegler et al. 2015a; Wilkerson et al. 2015; Harmsen et al. 2021), and comparison with historical patterns (Wilson et al. 2013; van Sluisveld et al. 2015; Napp et al. 2017).

A.III.1.9.2 Components of Integrated Assessment Models

A.III.1.9.2.1 Energy-economy Component

Typically, IAMs comprise a model of energy flows, emissions and the associated costs (Krey 2014). The demand for exploring the Paris Agreement climate goals led to model developments to make the challenges and opportunities of the associated transformation pathways more transparent. Since AR5 much progress has been achieved to improve the representation of mitigation options in the energy supply sector (e.g., renewable energy integration (Pietzcker et al. 2017), energy trade (Bauer et al. 2016; McCollum et al. 2016; Bauer et al. 2017; Jewell et al. 2018), capacity inertia, carbon removals, and decarbonisation bottlenecks (Luderer et al. 2018)) and technological and behavioural change measures in energy demand sectors such as transport (van Sluisveld et al. 2016; Edelenbosch et al. 2017a; McCollum et al. 2017). An energy sector model can be run as a partial equilibrium model using exogenous demand drivers for final energy and energy services. These models derive mitigation policy costs in terms of additional energy sector costs and area under the marginal abatement costs curve.

Energy models can be also embedded into a broader, long-term macroeconomic context in a general equilibrium model (Bauer et al. 2008; Messner and Schrattenholzer 2000). The demands for final energy and energy services are endogenously driven by an economic growth model that also endogenises the economic allocation problem of macroeconomic resources for the energy sector that crowd out with alternatives. This allows impact analysis of climate policies on economic growth and structural change, investment financing and crowding out as well as income distribution and tax revenue recycling (Guivarch et al. 2011). Moreover, general equilibrium models also derive mitigation costs in terms of GDP losses and consumption losses, which comprise the full macroeconomic impacts rather than only the narrow energy-related costs (Paltsev and Capros 2013).

A.III.1.9.2.2 Land System Component

In recent years, substantial efforts have been devoted to improve and integrate land-use sector models in IAMs (Popp et al. 2014b, 2017). This acknowledges the importance of land-use GHG emissions of the agricultural and forestry sectors as well as the role of bioenergy, afforestation and other land-based mitigation measures. The integration is particularly important in light of the long-term climate goals of the Paris Agreement, for four reasons (IPCC 2019b). First, the GHG emissions from land-use change account for more than 10% of global GHG emissions (Kuramochi

et al. 2020) and some sources of CH₄ and N₂O constitute serious mitigation bottlenecks. Second, bioenergy is identified as a crucial primary energy source for low-emission energy supply and carbon removal (Bauer et al. 2020a; Butnar et al. 2020; Calvin et al. 2021). Third, land use-based mitigation measures such as afforestation and reduced deforestation have substantial mitigation potentials. Finally, land-cover changes alter the Earth surface albedo, which has implications for regional and global climate. Pursuing the Paris Agreement climate goals requires the inclusion of a broad set of options regarding GHG emissions and removals, which will intensify the interaction between the energy sector, the economy and the land use sector. Consequently, intersectoral policy coordination becomes more important and the land-related synergies and trade-offs with sustainable development targets will intensify (Calvin et al. 2014b; Kreidenweis et al. 2016; Frank et al. 2017; van Vuuren et al. 2017a; Humpenöder et al. 2018; Bauer et al. 2020d). IAMs used by the IPCC in the AR6 have continuously improved the integration of land-use models with energy models to explore climate mitigation scenarios under varying policy and technology conditions (Rogelj et al. 2018a; Smith et al. 2019). However, feedbacks from changes in climate variables are not included in the land-use sector models, or are only included to a limited degree.

A.III.1.9.2.3 Climate System Component

Reduced complexity climate models (often called simple climate models or emulators) are used for communicating WGI physical climate science knowledge to the research communities associated with other IPCC working groups (Annex III.1.8). They are used by IAMs to model the climate outcome of the multi-gas emissions trajectories that IAMs produce (van Vuuren et al. 2011a). A main application of such models is related to scenario classifications in WGIII (Clarke et al. 2014; Rogelj et al. 2018a). Since WGIII assesses a large number of scenarios, it must rely on the use of these simple climate models; more computationally demanding models (as used by WGI) will not be feasible to apply. For consistency across the AR6 reports, it is important that these reduced-complexity models are up to date with the latest assessments from WGI. This relies on calibrating these models so that they match, as closely as possible, the assessments made by WGI (Annex III.1.2.5.1). The calibrated models can then be used by WGIII in various parts of its assessment.

A.III.1.9.3 Representation of Nexus Issues and Sustainable Development Impacts in Integrated Assessment Models

An energy-water-land nexus approach integrates the analysis of linked resources and infrastructure systems to provide a consistent platform for multi-sector decision-making (Howells et al. 2013). Many of the IAMs that contributed to the assessment incorporate a nexus approach that considers simultaneous constraints on land, water and energy, as well as important mutual dependencies (Fricko et al. 2017; Fujimori et al. 2017; Calvin et al. 2019; Dietrich et al. 2019; van Vuuren et al. 2019). Recently IAMs have also been integrated with life cycle assessment tools in assessing climate mitigation policies to better understand the relevance of life cycle GHG emissions in cost-optimal mitigation scenarios (Portugal-Pereira et al. 2016; Pehl et al. 2017;

Arvesen et al. 2018; Tokimatsu et al. 2020). This holistic perspective ensures mitigation pathways do not exacerbate challenges for other sectors or environmental indicators. At the same time, pathways are leveraging potential synergies along the way towards achieving multiple goals.

IAMs rely on biophysical models with a relatively high degree of spatial and temporal resolution to inform coarser-scale economic models of the potentials and costs for land, water and energy systems (Johnson et al. 2019). IAMs leverage population, GDP and urbanisation projections to generate consistent water, energy and crop demand projections across multiple sectors (e.g., agriculture, livestock, domestic, manufacturing and electricity generation) (Mouratiadou et al. 2016). The highly distributed nature of decisions and impacts across sectors, particularly for land and water, has been addressed using multi-scale frameworks that embed regional and sub-regional models within global IAMs (Mosnier et al. 2014; Hejazi et al. 2015; Bijl et al. 2018; Portugal-Pereira et al. 2018). These analyses have demonstrated how local constraints and policies interact with national and international strategies aimed at reducing emissions.

Sustainable development impacts extending beyond climate outcomes have been assessed by the IAMs that contributed to the assessment, particularly in the context of the targets and indicators consistent with the Sustainable Development Goals (SDGs). The representation of individual SDGs is diverse (Figure 3), and recent model development has focused mainly on improving capabilities to assess climate change mitigation policy combined with indicators for economic growth, resource access, air pollution and land use (van Soest et al. 2019). Synergies and trade-offs across sustainable development objectives can be quantified by analysing multi-sector impacts across ensembles of IAM scenarios generated from single or multiple models (McCollum et al. 2013; Mouratiadou et al. 2016). Modules have also been developed for IAMs with the specific purpose of incorporating policies that address non-climatic sustainability outcomes (Cameron et al. 2016; Fujimori et al. 2018; Parkinson et al. 2019). Similar features have been utilised to incorporate explicit adaptation measures and targeted policies that balance mitigation goals with other sustainability criteria (Bertram et al. 2018; McCollum et al. 2018).

A.III.1.9.4 Policy Analysis with IAMs

A key purpose of IAMs is to provide orientation knowledge for the deliberation of future climate action strategies by policymakers, civil society and the private sector. This is done by presenting different courses of actions (climate change and climate action pathways) towards a variety of long-term climate outcomes under a broad range of assumptions about future socio-economic, institutional and technological developments. The resulting climate change and climate action pathways can be analysed in terms of their outcomes towards a set of societal goals (such as the SDGs) and the resulting trade-offs between different pathways. Key trade-offs that have been investigated in the IAM literature are between (i) no, moderate, and ambitious mitigation pathways (Riahi et al. 2017), (ii) early vs delayed mitigation action (Riahi et al. 2015; Luderer et al. 2018), (iii) global action with a focus on economic efficiency equalising

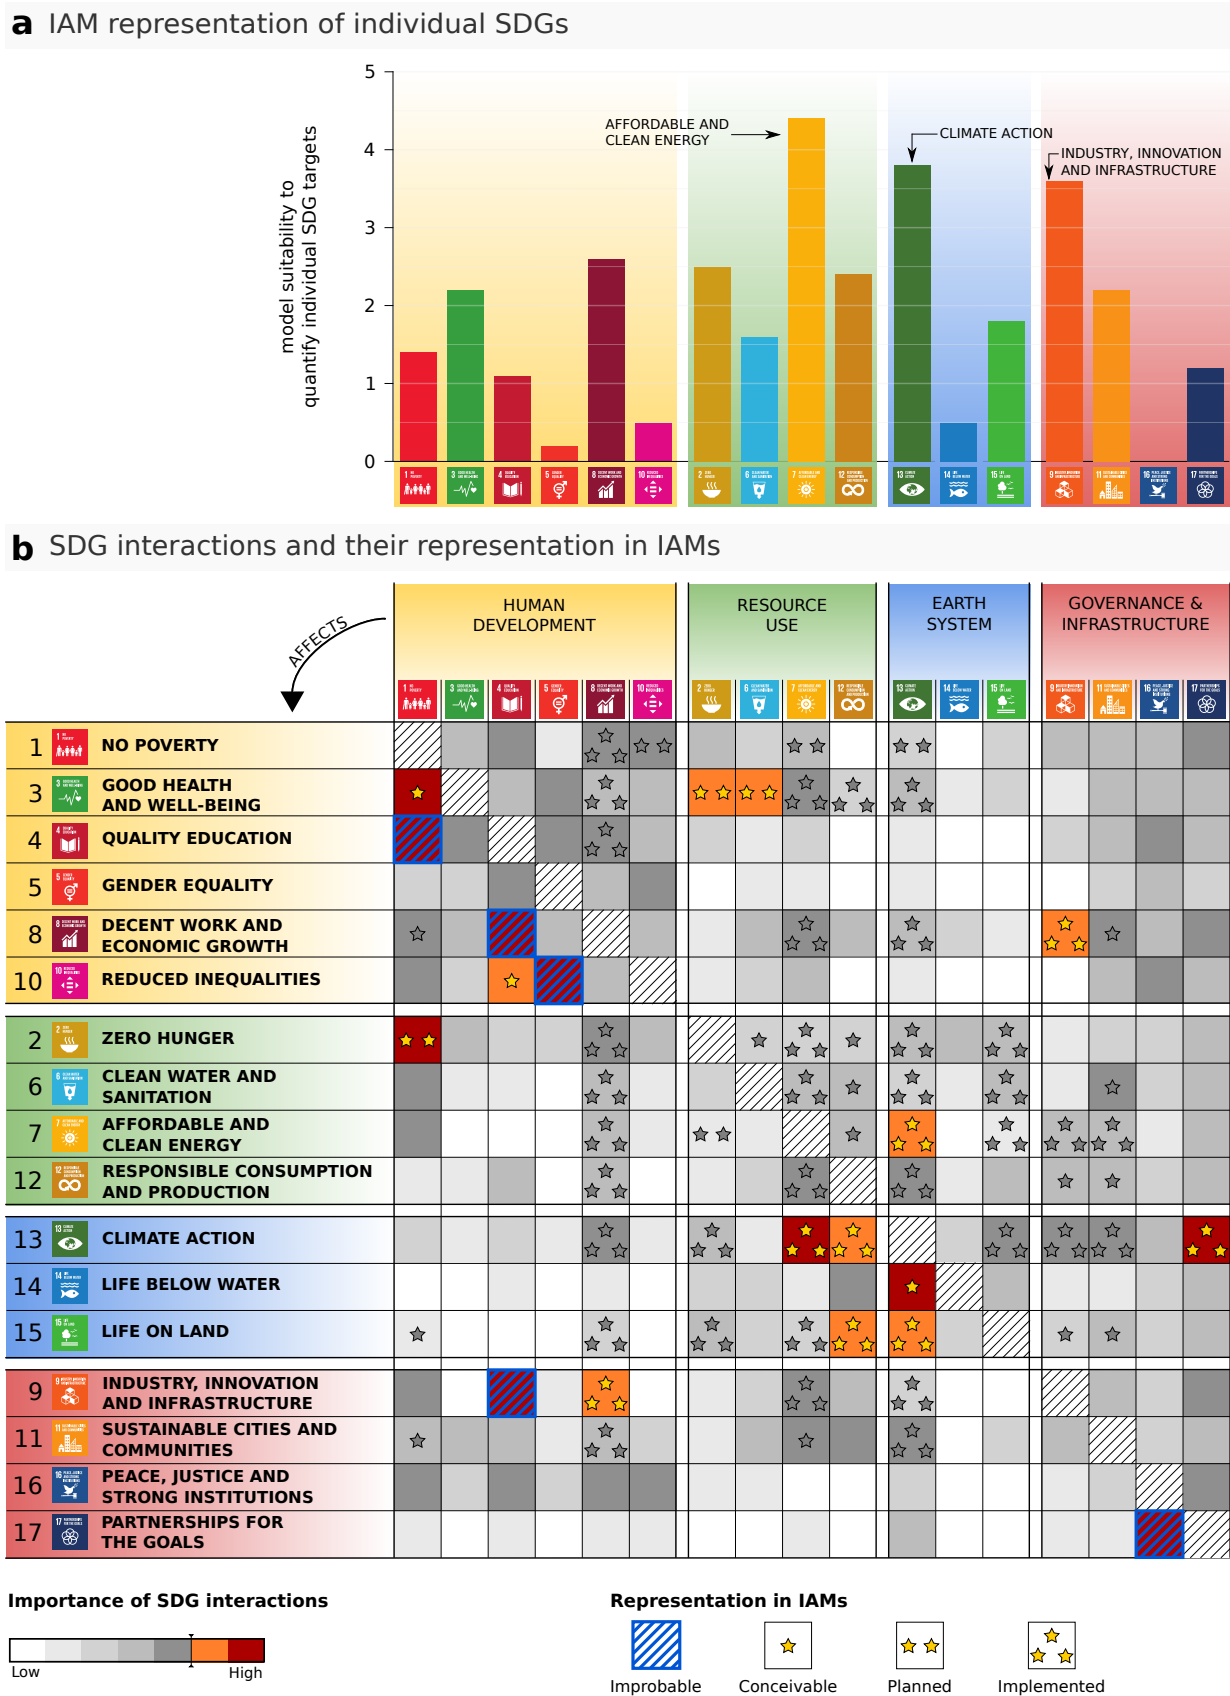

Figure 3 | The representation of Sustainable Development Goals by Integrated Assessment Models. (a) Individual target coverage from a multi-model survey; and (b) SDG interactions and coverage by IAM models according to a combination of expert and model surveys. The strength dimension of SDG interactions is indicated by grey shading: darker shades represent strong interactions while white represents no interactions. Orange cells indicate where there is the highest agreement between the importance of interactions and model representation, while blue coloured cells show the most important interactions without model representation. Source: van Soest et al. (2019).

marginal abatement costs across countries and sectors vs regionally and sectorally fragmented action (Blanford et al. 2014a; Bertram et al. 2015; Kriegler et al. 2015b, 2018b; Bauer et al. 2020b; Roelfsema et al. 2020), (iv) pathways with different emphasis on supply-side vs demand-side mitigation measures (Grubler et al. 2018; van Vuuren et al. 2018) or more broadly different sustainable development strategies (Riahi et al. 2012; van Vuuren et al. 2015; Soergel et al. 2021), and (v) pathways with different preferences about technology deployment, in particular with regard to carbon capture and storage (CCS) and carbon dioxide removal (CDR) (Krey 2014; Kriegler et al. 2014a; Riahi et al. 2015; Streffler et al. 2018; Rose et al. 2020; Luderer et al. 2021; Streffler et al. 2021b). Key uncertainties that were explored in the IAM literature are between (i) different socio-economic futures as, for example, represented by the Shared Socio-economic Pathways (SSPs) (Bauer et al. 2017; Popp et al. 2017; Riahi et al. 2017), (ii) different technological developments (Bosetti et al. 2015) and (iii) different resource potentials (Kriegler et al. 2016).

Policy analysis with IAMs follows the approach that a baseline scenario is augmented by some kind of policy intervention. To address the uncertainties in baseline projections, the scientific community has developed the Shared Socio-economic Pathways (SSPs) that provide a set of vastly different future developments as reference cases (Annex III.I.1.3,2). Most scenarios used in AR6 are based on the middle-of-the-road reference system (SSP2). Depending on the research interest, the baseline can be defined as a no-policy baseline or it can include policies that either address GHG emissions like the nationally determined contributions (NDCs) or other pre-existing policies such as energy subsidies and taxes. There is no standard definition for baseline scenarios regarding the inclusion of policies. The baseline scenario is augmented by additional policies like a carbon tax aiming towards a long-term climate goal. Hence, the IAM-based policy analysis assumes a reference system like SSP2 within which policy scenarios are compared with a baseline scenario.

Most policy analysis with process-based IAMs apply a mix of short-term policy evaluation and long-term policy optimisation. Policy evaluation applies an exogenous set of policies such as the stated NDCs and evaluates the emission outcomes. Policy optimisation is mostly implemented as a cost-effectiveness analysis: a long-term climate stabilisation target is set to derive the optimal mitigation strategy that equalises marginal abatement cost across sectors, GHGs and countries. This optimal mitigation strategy can be implemented by a broad set of well-coordinated sector-specific policies or by comprehensive carbon-pricing policies.

Most commonly, the baseline scenario is either a no-policy baseline or based on the NDCs applying an extrapolation beyond 2030 (Grant et al. 2020; Roelfsema et al. 2020). The climate policy regimes most commonly applied include a long-term target to be reached. The optimal climate strategy can be phased in gradually or applied immediately after 2020. It can focus on a global carbon price equalising marginal abatement costs across countries or policy intensities can vary across countries and sectors in the near to medium term. The climate policy regime can include or exclude effort-sharing mechanisms and transfers between regions. Also, it can be extended to include additional sector policies such as improved forest protection

or fossil fuel subsidy removal. If certain technologies or activities are related to spill-overs such as technology learning, carbon pricing might be complemented by technology support (Schultes et al. 2018). If carbon-pricing policies are fragmented or delayed, additional and early sector policies can help reduce distortions and carbon leakage effects (Bauer et al. 2020b). All these variations to the policy regime can lead to very different transformation pathways and policy costs, which is a core result of the IAM analysis.

By applying sensitivity analysis, IAMs can be used to assess the importance of strategically developing new technologies and options for mitigation and identifying sticking points in climate policy frameworks. The sensitivity analysis evaluates differences in outcomes subject to changes in assumptions. For instance, the assumption about the timing and costs of CCS and CDR availability can be varied (Bauer et al. 2020a). The differences in mitigation costs and the transformation pathways support the assessment of policy prioritisation by identifying and quantifying crucial levers for achieving long-term climate mitigation targets such as R&D efforts and timing of policies.

A.III.I.9.5 Limitations of IAMs

The application of IAMs and their results for providing knowledge on climate change response strategies have been criticised based on four arguments (Gambhir et al. 2019; Keppo et al. 2021). First, there are concerns that IAMs are missing important dynamics, for example with regard to climate damages and economic co-benefits of mitigation (Stern 2016), demand-side responses (Wilson et al. 2012), bioenergy, land degradation and management (Creutzig et al. 2015; IPCC 2019b), carbon dioxide removal (Smith et al. 2016), rapid technological progress in the renewable energy sector (Creutzig et al. 2017), actor heterogeneity, and distributional impacts of climate change and climate policy. This has given rise to criticism that IAMs lack credibility in a set of crucial assumptions, among which stands out the critique on the availability of carbon dioxide removal technologies (Anderson and Peters 2016; Bednar et al. 2019).

These concerns spur continuous model development and improvements in scenario design (Keppo et al. 2021), particularly with regard to improved representations of energy demand, renewable energy, carbon dioxide removal technologies, and land management. IAMs are aiming to keep pace with the development of sector-specific models, including latest advances in estimating and modelling climate damages (Piontek et al. 2019). In places, where dynamic modelling approaches are lacking, scenarios are being used to explore relevant futures (Grubler et al. 2018). Moreover, sector-specific model comparison studies have brought together domain experts and modellers to improve model representations in these areas (Edelenbosch et al. 2017a; Pietzcker et al. 2017; Bauer et al. 2020a; Harmsen et al. 2020; Rose et al. 2020). Although most models are still relying on the concept of a single representative household representing entire regions, efforts are under way to better represent agent heterogeneity and distributional impacts of climate change and climate mitigation policies (Rao et al. 2017a; Peng et al. 2021).

Second, concerns have been raised that IAMs are non-transparent and thus make it difficult to grasp the context and meaning of their results (Skea et al. 2021). These concerns have facilitated a substantial increase in model documentation (see the common IAM documentation at www.iamcdocumentation.eu as an entry point) and open-source models. Nonetheless, more communication tools and co-production of knowledge formats will be needed to contextualise IAM results for users (Auer et al. 2021). When projecting over a century, uncertainties are large and cannot be ignored. Efforts have been undertaken (Marangoni et al. 2017; Gillingham et al. 2018; Harmsen et al. 2021; Wilson et al. 2021) to diagnose key similarities and differences between models and better gauge robust findings from these models and how much they depend on key assumptions (such as, for example, long-term growth of the economy, the monetary implication of climate damages, or the diffusion and cost of key mitigation technologies).

Third, there are concerns that IAMs are describing transformative change on the level of energy and land use, but are largely silent about the underlying socio-cultural transitions that could imply restructuring of society and institutions. Weyant (2017) notes the inability of IAMs to mimic extreme and discontinuous outcomes related to these underlying drivers as one of their major limitations. This is relevant when modelling extreme climate damages as well as when modelling disruptive changes. Dialogues and collaborative work between IAM researchers and social scientists have explored ways to bridge insights from the various communities to provide a more complete picture of high-impact climate change scenarios and, on the other end, deep transformation pathways (Turnheim et al. 2015; Geels et al. 2016; Trutnevyte et al. 2019). The extension of IAM research to sustainable development pathways is giving rise to further inter-disciplinary research on underlying transformations towards the Paris climate goals and other sustainable development goals (Kriegler et al. 2018c; Sachs et al. 2019b).

Finally, there are concerns that IAM analysis could focus on only a subset of relevant futures and thus push society in certain directions without sufficient scrutiny (Beck and Mahony 2017). IAMs aim to explore a wide range of socio-economic, technology and policy assumptions (Riahi et al. 2017), but it remains a constant challenge to capture all relevant perspectives (O'Neill et al. 2020). These concerns can be addressed by adopting an iterative approach between researchers and societal actors in shaping research questions and IAM applications (Edenhofer and Kowarsch 2015). IAM research is constantly taking up concerns about research gaps and fills it with new pathway research, as, for example, occurred for low energy demand and limited bioenergy with CCS scenarios (Grubler et al. 2018; van Vuuren et al. 2018).

A.III.I.10 Key Characteristics of Models that Contributed Mitigation Scenarios to the Assessment²

Table 5 | Comparison of modelling characteristics as stated by contributing modelling teams to the AR6 database. Attributes include regional scope, sectoral coverage, type of baseline or benchmark setup as a basis for mitigation policies comparison, technology diffusion, capital vintaging and 'sunsetting' of technologies and variety of discount rates approaches.

A.III.I.11 Comparison of Mitigation and Removal Measures Represented by Models that Contributed Mitigation Scenarios to the Assessment³

Table 7 | Overview of demand- and supply-side mitigation and removal measures in the energy, transport, building, industry and AFOLU sectors, as stated by contributing modelling teams to the AR6 database. Levels of inclusion were classified in two dimensions of explicit versus implicit and endogenous or exogenous. An explicit level suggests that the measure is directly represented in the model, while an implicit level refers to measures that are estimated indirectly by a proxy. An endogenous level reflects measures that are included in the dynamics of the model framework, whereas an exogenous level refers to measures that are not part of the model dynamics.

Part II: Scenarios

A.III.II.1 Overview on Climate Change Scenarios

Scenarios are descriptions of alternative future developments. They are used to explore the potential implications of possible future developments and how they might depend on alternative courses of action. They are particularly useful in the context of deep uncertainty. Scenarios are conditional on the realisation of external assumptions and can be used to explore possible outcomes under a variety of assumptions.

Future climate change is a prime example for the application of scenarios. It is driven by human activities across the world and thus can be altered by human agency. It affects all regions over many centuries to come. Humankind's response to climate change touches not only on the way we use energy and land, but also on socio-economic and institutional layers of societal development. Climate change scenarios provide a central tool to analyse this wicked problem.

A.III.II.1.1 Purposes of Climate Change Scenarios

Climate change scenarios are developed for a number of purposes (O'Neill et al. 2020). First, they are constructed to explore possible climate change futures covering the causal chain from (i) socio-economic developments to (ii) energy and land use to (iii) greenhouse gas emissions to (iv) changes in the atmospheric composition of greenhouse gases and short-lived climate forcers and the associated radiative forcing to (v) changes in temperature and precipitation patterns to (vi) bio-physical impacts of climate change and finally to (vii) impacts on socio-economic developments, thus closing the loop. Quantitative scenarios exploring possible climate change futures are often called climate change projections and climate change impact projections.

Second, climate change scenarios are developed to explore pathways towards long-term climate goals. Goal-oriented scenarios often carry the word 'pathway' in their name, such as climate change mitigation pathway, climate change adaptation pathway, or more generally climate change transition or transformation pathway. They are sometimes called 'backcasting'⁴ scenarios, or 'short backcasts', in the literature, particularly when contrasted with forecasts (Robinson 1982). Goal-oriented/backcasting scenarios are inherently normative and intricately linked to human intervention. They can be used to compare and contrast different courses of actions. For example, they are applied in climate change mitigation analysis by comparing reference scenarios without or with only moderate climate policy intervention, sometimes called baseline scenarios, with mitigation pathways that achieve certain climate goals (Grant et al. 2020). Transformation pathways to climate goals are examples of backcasting scenarios. Among other things, they can be used to learn about the multi-dimensional trade-offs between raising or lowering

ambition (Clarke et al. 2014; Schleussner et al. 2016). In addition, different transformation pathways to the same goal are often used to analyse trade-offs between different routes towards this goal (Rogelj et al. 2018a). These scenarios need to be looked at as a set to understand attainable outcomes and the trade-offs between them. With scenarios, context matters.

Third, climate change scenarios are used to integrate knowledge and analysis between the three different climate change research communities working on the climate system and its response to human interference (linked to WG I of the IPCC), climate change impacts, adaptation and vulnerability (linked to WGII) and climate change mitigation (linked to WGIII) (O'Neill et al. 2016; IPCC 2000; van Vuuren et al. 2011b) (Annex III.II.1.3). This involves the adoption of common scenario frameworks that allow the consistent use of, for example, shared emissions scenarios, socio-economic development scenarios and climate change projections (Moss et al. 2010; Kriegler et al. 2012; van Vuuren et al. 2012; O'Neill et al. 2014; van Vuuren et al. 2014). The integrative power of scenarios extends beyond the climate change research community into neighbouring fields such as the social sciences and ecology (Pereira et al. 2020; Rosa et al. 2020). To foster such integration, underlying scenario narratives have proven extremely useful as they allow researchers to develop and link quantitative scenario expressions in very different domains of knowledge (O'Neill et al. 2020).

Fourth, climate change scenarios and their assessment aim to inform society (Kowarsch et al. 2017; Weber et al. 2018; Auer et al. 2021). To achieve this, it is important to connect climate change scenarios to broader societal development goals (Riahi et al. 2012; van Vuuren et al. 2015; Kriegler et al. 2018c; Soergel et al. 2021) and relate them to social, sectoral and regional contexts (Absar and Preston 2015; Frame et al. 2018; Kok et al. 2019; Aguiar et al. 2020). To this end, scenarios can be seen as tools for societal discourse and decision-making to coordinate perceptions about possible and desirable futures between societal actors (Edenhofer and Kowarsch 2015; Beck and Mahony 2017).

A.III.II.1.2 Types of Climate Change Mitigation Scenarios

Different types of climate change scenarios are linked to different purposes and knowledge domains and different models are used to construct them (Annex III.I). Global reference and mitigation scenarios and their associated emissions projections, which are often called emission scenarios, and national, sector and service transition scenarios are key types of scenarios assessed in the Working Group III report. They are briefly summarised below.⁵

A brief description of the common climate change scenario framework with relevance for all three IPCC Working Groups is provided in Annex III.II.1.3, and a discussion how the WGI and WGII assessments relate to the WGIII scenario assessment is given in Annex III.II.2.5.

⁴ Backcasting is different from hindcasting. Hindcasting refers to testing the ability of a mathematical model to reproduce past events. In contrast, backcasting begins with a desired future outcome and calculates a pathway from the present to that outcome consistent with constraints.

⁵ The terms mitigation/transition/transformation scenarios and mitigation/transition/transformation pathways are used interchangeably, as they refer to goal-oriented scenarios.

A.III.II.1.2.1 *Global mitigation scenarios*

Global mitigation scenarios are mostly derived from global integrated assessment models (Annex III.I.9) and have been developed in single model studies as well as multi-model comparison studies. The research questions of these studies have evolved together with the climate policy debate and the knowledge about climate change, drivers, and response measures. The assessment of global mitigation pathways in the Fifth Assessment Report (AR5) (Clarke et al. 2014) was informed, *inter alia*, by a number of large-scale multi-model studies comparing overshoot and not-to-exceed scenarios for a range of concentration stabilisation targets (Energy Modelling Forum (EMF) study 22: EMF22) (Clarke et al. 2009), exploring the economics of different decarbonisation strategies and robust characteristics of the energy transition in global mitigation pathways (EMF27, RECIPE) (Luderer et al. 2012; Krey and Riahi 2013; Kriegler et al. 2014a), and analysing co-benefits and trade-offs of mitigation strategies with energy security, energy access, and air quality objectives (Global Energy Assessment: GEA) (McCollum et al. 2011; Riahi et al. 2012; McCollum et al. 2013; Rao et al. 2013; Rogelj et al. 2013b). They also investigated the importance of international cooperation for reaching ambitious climate goals (EMF22, EMF27, AMPERE) (Clarke et al. 2009; Blanford et al. 2014b; Kriegler et al. 2015b), the implications of collective action towards the 2°C goal from 2020 onwards vs delayed mitigation action (AMPERE, LIMITS) (Kriegler et al. 2014b; Riahi et al. 2015), and the distribution of mitigation costs and burden-sharing schemes in global mitigation pathways (LIMITS) (Tavoni et al. 2014, 2015). Scenarios from these and other studies were collected in a scenario database supporting the AR5 assessment (Krey et al. 2014). With a shelf life of 8 to 14 years, they are now outdated and no longer part of this assessment.

Since AR5, many new studies published global mitigation pathways and associated emissions projections. After the adoption of the Paris Agreement, several large-scale multi-model studies newly investigated pathway limiting warming to 1.5°C (ADVANCE: Luderer et al. (2018); CD-LINKS: McCollum et al. (2018a); ENGAGE: Riahi et al. (2021); SSPs: Rogelj et al. (2018b)), allowing this report to conduct a robust assessment of 1.5°C pathways. Most scenario studies took the hybrid climate policy architecture of the Paris Agreement with global goals, nationally determined contributions (NDCs) and an increasing number of implemented national climate policies as a starting point, including hybrid studies with participation of global and national modelling teams to inform the global stocktake (ENGAGE: Fujimori et al. (2021); COMMIT: van Soest et al. (2021); CD-LINKS: Schaeffer et al. (2020), Roelfsema et al. (2020)). Multi-model studies covered a range of scenarios from extrapolating current policy trends and the implementation of NDCs, respectively, to limiting warming to 1.5°C–2°C with immediate global action and after passing through the NDCs in 2030, respectively. These scenarios are used to investigate, among others, the end-of-century warming implications of extrapolating current policy trends and NDCs (Perdana et al. 2020); the ability of the NDCs to keep limiting warming to 1.5°C–2°C in reach (Luderer et al. 2018; Vrontisi et al. 2018; Roelfsema et al. 2020), the scope for global accelerated action to go beyond the NDCs in 2030 (van Soest et al. 2021), and the benefits of early action vs the risk of overshoot and the use of net negative CO₂ emissions in the long-

term (Bertram et al. 2021; Hasegawa et al. 2021; Riahi et al. 2021). Other large-scale multi-model studies looked into specific topics: the international economic implications of the NDCs in 2030 (EMF36) (Böhringer et al. 2021), the impact of mitigating short-lived climate forcers on warming and health co-benefits in mitigation pathways (EMF30) (Harmsen et al. 2020; Smith et al. 2020b) and the role and implications of large-scale bioenergy deployment in global mitigation pathways (EMF33) (Bauer et al. 2020a; Rose et al. 2020).

A large variety of recent modelling studies, mostly based on individual models, deepened research on a diverse set of questions (Annex III. II.3.2). Selected examples are the impact of peak vs end-of-century targets on the timing of action in mitigation pathways (Rogelj et al. 2019a; Streffler et al. 2021a); demand-side driven deep mitigation pathways with sustainable development co-benefits (Bertram et al. 2018; Grubler et al. 2018; van Vuuren et al. 2018); synergies and trade-offs between mitigation and sustainable development goals (Fujimori et al. 2020; Soergel et al. 2021); and the integration of climate impacts into mitigation pathways (Schultes et al. 2021). There have also been a number of recent sectoral studies with global integrated assessment models and other global models across all sectors, for example the energy sector (IRENA 2020; Kober et al. 2020; IEA 2021) and transport sector (Edelenbosch et al. 2017a; Mercure et al. 2018; Zhang et al. 2018; Fisch-Romito and Guivarch 2019; Rottoli et al. 2021; Lam and Mercure 2021; Paltsev et al. 2022). Very recent work investigated the impact of COVID-19 on mitigation pathways (Kikstra et al. 2021a) and co-designed global scenarios for users in the financial sector (NGFS 2021). In addition to these policy-, technology- and sector-oriented studies, a few diagnostic studies developed mitigation scenarios to diagnose model behaviour (Harmsen et al. 2021) and explore model harmonisation (Giarola et al. 2021).

The scenarios from most of these and many other studies were collected in the AR6 scenario database (Annex III.II.3.2) and are primarily assessed in Chapter 3 of the report. However sectoral chapters have also used the scenarios, including their climate mitigation categorisations, to ensure consistent cross-chapter treatment. Only a small fraction of these scenarios were already available to the assessment of global mitigation pathways in the Special Report on Global Warming of 1.5°C (SR1.5) (Rogelj et al. 2018a) and were included in the supporting SR1.5 database (Huppmann et al. 2018).

A.III.II.1.2.2 *National Transition Scenarios*

A large number of transition scenarios is developed on a national/regional level by national integrated assessment, energy-economy or computable general equilibrium models, among others. These aim to analyse the implications of current climate plans of countries and regions, as well as long-term strategies until 2050 investigating different degrees of low-carbon development. National/regional transition scenarios are assessed in Chapter 4 of the report.

Recent research has focused on several different types of national transition scenarios that focus on accelerated climate mitigation pathways in the near term to 2050. These include scenarios considered

by the authors as tied to meeting specific global climate goals⁶ and scenarios tied to specific policy targets (e.g., carbon neutrality or 80–95% reduction from a certain baseline year). A majority of the accelerated national transition modelling studies up to 2050 evaluate pathways that the authors consider compatible with a 2°C global warming limit, with fewer scenarios defined as compatible with 1.5°C global pathways. Regionally, national transition scenarios have centred on countries in Asia (particularly in China, India, Japan), in the European Union, and in North America, with fewer and more narrowly focused scenario studies in Latin America and Africa (Lepault and Lecocq 2021).

A.III.II.1.2.3 Sector Transition Scenarios

There are also a range of sector transition scenarios, both on the global and the country level. These include scenarios for the transition of the electricity, buildings, industry, transport and AFOLU sectors until 2050. Due to the accelerated electrification in mitigation pathways, sector coupling plays an increasingly important role to overcome decarbonisation bottlenecks, complicating a separate sector-by-sector scenario assessment. Likewise, the energy-water-land nexus limits the scope of a separate assessment of the energy and agricultural sectors. Nevertheless, sector transition scenarios play an important role for this assessment as they can usually offer much more technology, policy and behaviour detail than integrated assessment models. They are primarily assessed in the sector chapters of the report. Their projections of emissions reductions in the sectors in the near to medium term is used to check the sector dynamics of global models in Chapter 3 of the report.

Recent transition scenarios considered overarching accelerated climate mitigation strategies across multiple sectors, including demand reduction, energy efficiency improvement, electrification and switching to low-carbon fuels. The sectoral strategies considered are often specific to national resource availability, political, economic, climate, and technological conditions. Many sectoral transition strategies have focused on the energy supply sectors, particularly the power sector, and the role for renewable and bio-based fuels in decarbonising energy supply and carbon capture and sequestration (CCS). Some studies present comprehensive scenarios for both supply-side and demand-side sectors, including sector-specific technologies, strategies, and policies. Nearly all demand sector scenarios have emphasised the need for energy efficiency, conservation and reduction through technological changes, with a limited number of models also exploring possible behavioural changes enabled by new technological and societal innovations.

A.III.II.1.2.4 Service Transition Scenarios

A central feature of service transition pathways is a focus on the provision of adequate energy services to provide decent standards of living for all as the main scenario objective. Energy services are proxies for well-being, with common examples being provision of shelter (expressed as m² per capita), mobility (expressed as passenger-kilometres), nutrition (expressed as kCal per capita), and

thermal comfort (expressed as degree-days) (Creutzig et al. 2018). Service transition pathways seek to meet adequate levels of such services with minimal carbon emissions, using combinations of demand- and supply-side options. Ideally this is done by improving the efficiency of service provision systems to minimise overall final energy and resource demand, thereby reducing pressure on supply-side and carbon dioxide removal technologies (Grubler et al. 2018). Specifically, this includes providing convenient access to end-use services (health care, education, communication, etc.), while minimising both primary and end-use energy required. Service transition pathways provide a compelling scenario narrative focused on well-being, resulting in technology and policy pathways that give explicit priority to decent living standards. Furthermore, more efficient service provision often involves combinations of behavioural, infrastructural and technological change, expanding the options available to policymakers for achieving mitigation goals (van Sluisveld et al. 2016, 2018). These dimensions are synergistic, in particular in that behavioural and lifestyle changes often require infrastructures adequately matching lifestyles. Service transition scenarios are primarily assessed in Chapter 5 of the report.

A.III.II.1.3 Scenario Framework for Climate Change Research

A.III.II.1.3.1 History of Scenario Frameworks used by the IPCC

For the first three assessment reports, the IPCC directly commissioned emission scenarios with social, economic, energy and partially policy aspects as drivers of projected GHG emissions. The first set of scenarios, the 'SA90' of the IPCC First Assessment Report (IPCC 1990), had four distinct scenarios, 'business-as-usual' and three policy scenarios of increasing ambition. The set of 'IS92' scenarios used in the Second Assessment Report investigated variations of business-as-usual scenarios with respect to uncertainties about the key drivers of economic growth, technology and population (Leggett et al. 1992). The SRES scenarios from the IPCC Special Report on Emission Scenarios (SRES) (IPCC 2000) were produced by multiple modelling organisations and were used in the Third and Fourth Assessment reports. Four distinct scenario families were characterised by narratives and projections of key drivers like population development and economic growth (but no policy measures) to examine their influence on a range of GHG and air pollutant emissions. Until the Fourth Assessment Report, the IPCC organised the scenario development process centrally. Since then, scenarios are developed by the research community and the IPCC limited its role to catalysing and assessing scenarios. To shorten development times, a parallel approach was chosen (Moss et al. 2010) and representative concentration pathways (RCPs) were developed (van Vuuren et al. 2011b) to inform the next generation of climate modelling for the Fifth Assessment Report. RCPs explored four different emissions and atmospheric composition pathways structured to result in different levels of radiative forcing in 2100: 2.6, 4.5, 6.0 and 8.5 W m⁻². They were used as an input to the Climate Model Intercomparison Project Phase 5 (CMIP5) (Taylor et al. 2011) and its results were assessed in AR5 (Collins et al. 2013).

⁶ National emission pathways in the near or mid-term cannot be linked to long-term mitigation goals without making additional assumptions about emissions by other countries up to the mid-term, and assumptions by all countries up to 2100 (see Chapter 4, Box 4.1).

A.III.II.1.3.2 Current Scenario Framework and SSP-based Emission Scenarios

The current scenario framework for climate change research (Kriegler et al. 2014c; O'Neill et al. 2014; van Vuuren et al. 2014) is based on the concept of Shared Socio-economic Pathways (SSPs) (Kriegler et al. 2012; O'Neill et al. 2014). Unlike their predecessor scenarios from the SRES (IPCC 2000), their underlying narratives are motivated by the purpose of using the framework for mitigation and adaptation policy analysis. Hence the narratives are structured to cover the space of socio-economic challenges to both adaptation and mitigation. They tell five stories of sustainability (SSP1), middle of the road development (SSP2), regional rivalry (SSP3), inequality (SSP4) and fossil-fuelled development (SSP5) (O'Neill et al. 2017). SSP1, SSP2, and SSP3 were structured to explore futures with socio-economic challenges to adaptation and mitigation increasing from low to high with increasing number of SSP. SSP4 was structured to explore a world with high socio-economic challenges to adaptation but low socio-economic challenges to mitigation, while SSP5 explored a world with low challenges to adaptation but high challenges to mitigation. The five narratives have been translated into population and education (Kc and Lutz 2017), economic growth (Crespo Cuaresma 2017; Dellink et al. 2017; Leimbach et al. 2017a), and urbanisation projections (Jiang and O'Neill 2017) for each of the SSPs.

The SSP narratives and associated projections of socio-economic drivers provide the core components for building SSP-based scenario families. These basic SSPs are not scenarios or goal-oriented pathways themselves (despite carrying 'pathway' in the name), but building blocks from which to develop full-fledged scenarios. In particular, their basic elements do not make quantitative assumptions about energy and land use, emissions, climate change, climate impacts and climate policy. Even though including these aspects in the scenario-building process may alter some of the basic elements, such as projections of economic growth, the resulting scenario remains associated with its underlying SSP. To improve the ability of SSPs to capture socio-economic environments, basic SSPs have been extended in various ways, including the addition of quantitative projections on further key socio-economic dimensions like inequality (Rao et al. 2019), governance (Andrijevic et al. 2020b), and gender equality (Andrijevic et al. 2020a). Extensions also included spatially downscaled projections of, for example, population developments (Jones and O'Neill 2016). By now, the SSPs have been widely used in climate change research ranging from projections of future climate change to mitigation, impact, adaptation and vulnerability analysis (O'Neill et al. 2020).

The integrated assessment modelling community has used the SSPs to provide a set of global integrated energy-land use-emissions scenarios (Bauer et al. 2017; Calvin et al. 2017; Fricko et al. 2017; Fujimori et al. 2017; Kriegler et al. 2017; Popp et al. 2017; Rao et al. 2017b; Riahi et al. 2017; van Vuuren et al. 2017b; Rogelj et al. 2018b) in line with the matrix architecture of the scenario framework (van Vuuren

et al. 2014) (Figure 4). It is structured along two dimensions: socio-economic assumptions varied along the SSPs, and climate (forcing) outcomes varied along the Representative Concentration Pathways (RCPs) (van Vuuren et al. 2011b). To distinguish resulting emission scenarios from the original four RCPs (RCP2.6, RCP4.5, RCP6.0, and RCP8.5), they are typically named SSPx-y with $x = \{1, \dots, 5\}$ the SSP label and $y = \{1.9, 2.6, 3.4, 4.5, 6.0, 7.0, 8.5\}$ W m⁻² the nominal forcing level in 2100. The four forcing levels that were already covered by the original RCPs are bolded here.

The new SSP-based emissions and concentrations pathways provided the input for CMIP6 (Eyring et al. 2015; O'Neill et al. 2016) and its climate change projections are assessed in AR6 (WGI Cross-chapter Box 1.2, WGI Chapter 4). From the original set of more than 100 SSP-based energy-land use-emissions scenarios produced by six IAMs (Figure 4), five Tier 1 scenarios (SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0, SSP5-8.5), and four Tier 2 scenarios (SSP4-3.4, SSP4-6.0, variants of SSP7-3.0, SSP5-3.4) were selected⁷ (O'Neill et al. 2016), further processed and harmonised with historic emissions and land-use change estimates (Gidden et al. 2019; Hurtt et al. 2020), and then taken up by CMIP6 models. WGI focuses its assessment of CMIP6 climate change projections on the five Tier 1 scenarios (WGI Chapter 4), but also uses the Tier 2 scenarios where they allow assessment of specific aspects like air pollution. All SSP-based IAM scenarios from the original studies are included in the AR6 emissions scenario database and are part of the assessment of global mitigation pathways in Chapter 3.

IAMs could not identify SSP-based emissions scenarios for all combinations of SSPs and RCPs (Riahi et al. 2017; Rogelj et al. 2018b) (Figure 4). The highest emission scenarios leading to forcing levels similar to RCP8.5 could only be obtained in a baseline without climate policy in SSP5 (SSP5-8.5). Since by now climate policies are implemented in many countries around the world, the likelihood of future emission levels as high as in SSP5-8.5 has become small (Ho et al. 2019). Baselines without climate policies for SSP1 and SSP4 reach up to 6.0–7.0 W m⁻², with baselines for SSP2 and SSP3 coming in higher at around 7.0 W m⁻². On the lower end, no 1.5°C (RCP1.9) and likely 2°C scenarios (RCP2.6) could be identified for SSP3 due to the lack of cooperative action in this world of regional rivalry. 1.5°C scenarios (RCP1.9) could only be reached by all models under SSP1 assumptions. Models struggled to limit warming to 1.5°C under SSP4 assumptions due to limited ability to sustainably manage land, and under SSP5 assumptions due to their high dependence on ample fossil fuel resources in the baseline (Rogelj et al. 2018b).

A.III.II.1.4 Key Design Choices and Assumptions in Mitigation Scenarios

The development of a scenario involves design choices, in addition to the selection of the model. This section will focus on key choices related to scenario design, and the respective socio-economic, technical, and

⁷ Each SSPx-y combination was calculated by multiple IAMs. The specific scenarios developed by the marker models for the associated SSPs (SSP1: IMAGE; SSP2: MESSAGE-GLOBIOM; SSP3: AIM; SSP4: GCAM; SSP5: REMIND-MAGPIE) were selected as Tier 1/Tier 2 scenarios for use in CMIP6. Tier 2 variants include SSP7-3.0 with high emissions of short-lived climate forcers and SSP5-3.4 with high overshoot from following SSP5-8.5 until 2040.

Figure 4 | The SSP/RCP matrix showing the SSPs on the horizontal axis and the forcing levels on the vertical axis. A = AIM, G = GCAM; I = IMAGE, M = MESSAGE-GLOBIOM, R = REMIND-MAGPIE, W = WITCH]. Not all SSP/RCP combinations are feasible (red triangles), and not all combinations were tried (grey triangles). Source: adapted with permission from Figure 5 of Rogelj et al. (2018b). Corresponding scenarios were published in Riahi et al. (2017) and Rogelj et al. (2018b) and included in the AR6 scenario database.

policy assumptions. Model selection cannot be separated from these choices. The various advantages and disadvantages of models are described in Annex III, Part I (Modelling Methods).

Target setting: Goal-oriented scenarios in the climate scenario literature initially focused on concentration stabilisation but have now shifted towards temperature limits and associated carbon budgets. In early model intercomparisons, climate targets were often specified as a CO₂-equivalent concentration level, for example, 450ppm CO₂-eq or 550ppm CO₂-eq (Clarke et al. 2009). These targets were either applied as not-to-exceed or overshoot targets. In the latter case, concentration levels could be returned to the target level by 2100. Overshoot was particularly allowed for low concentration and temperature targets as many models could not find a solution otherwise (Clarke et al. 2009; Blanford et al. 2014b; Kriegler et al. 2014a; Rogelj et al. 2018b). Bioenergy with carbon capture and storage (BECCS) was an important technology that facilitated aggressive targets to be met in 2100. Due to its ability to remove CO₂ from the atmosphere and produce net negative CO₂ emissions, it enabled overshoot of the target, leading to a distinctive peak-and-decline behaviour in concentration, radiative forcing, and temperature (Clarke et al. 2014; Fuss et al. 2014). The mitigation

scenarios based on the SSP-RCP framework also applied radiative forcing levels in 2100 (Riahi et al. 2017). Temperature targets were often implemented by imposing end-of-century carbon budgets, that is, cumulative emissions up until 2100. In the case of 2°C pathways, those budgets were usually chosen such that the 2°C limit was not overshoot with some pre-defined probability (Luderer et al. 2018). Arguably, the availability of net negative CO₂ emissions has led to high levels of carbon dioxide removal (CDR) in the second half of the century, although CDR deployment is often already substantial to compensate residual emissions (Rogelj et al. 2018a).

Recent literature has increasingly focused on alternative approaches such as peak warming or peak CO₂ budget constraints to implement targets (Rogelj et al. 2019b; Johansson et al. 2020; Riahi et al. 2021). Nevertheless, due to the availability of net negative CO₂ emissions and the assumption of standard (exponentially increasing) emissions-pricing profiles from economic theory, peak and decline temperature profiles still occurred in a large number of mitigation pathways in the literature even in the presence of peak warming and carbon budget targets (Strefler et al. 2021b). This has led to proposals to combine peak targets with additional assumptions affecting the timing of emissions reductions like a constraint on net negative CO₂

emissions (Obersteiner et al. 2018; Rogelj et al. 2019a; Riahi et al. 2021) and different carbon pricing profiles (Strefler et al. 2021b). These proposals are aiming at a stabilisation rather than a peak and decline of warming under a given warming limit. However, arguments in support of peak and decline warming profiles also exist: the goal of hedging against positive feedback loops in the Earth system (Lenton et al. 2019) and the aim of increasing the likelihood of staying below a temperature limit towards the end of the century (Schleussner et al. 2016). It is also noteworthy that peak and decline temperature pathways are connected to achieving net-zero GHG emissions (with CO₂-eq emissions calculated using GWP100) in the second half of the century (Rogelj et al. 2021).

Efficiency considerations: Process-based IAMs typically calculate cost-effective mitigation pathways towards a given target as a benchmark case (Clarke et al. 2014). In these pathways, global mitigation costs are minimised by exploiting the abatement options with the least marginal costs across all sectors and regions at any time, implicitly assuming a globally integrated and harmonised mitigation regime. This idealised benchmark is typically compared across different climate targets or with reference scenarios extrapolating current emissions trends (UNEP 2019). It naturally evolves over time as the onset of cost-effective action is being set to the immediate future of respective studies. This onset was pushed back from 2010–2015 in studies assessed by AR5 (Clarke et al. 2014) to the first modelling time step after 2020 in studies assessed by AR6.

The notion of cost-effectiveness is sensitive to economic assumptions in the underlying models, particularly concerning the assumptions on pre-existing market distortions (Guivarch et al. 2011; Clarke et al. 2014; Krey et al. 2014) and the discount rate on future values. Those assumptions are often not clearly expressed. Most models have a discount rate of 3–5%, though the range of alternatives is larger. Cost-benefit IAMs have had a tradition of exploring the importance of discount rates, but process-based IAMs have generally not. A lower discount rate brings mitigation forward in time and uses less net negative CO₂ emissions in cases where target overshoot is allowed (Emmerling et al. 2019; Realmonte et al. 2019). While most models report discount rates in documentation, there is arguably too little sensitivity analysis of how the discount rate affects modelled outcomes.

Cost-effective pathways typically do not account for climate impacts below the temperature limit, although recent updates to climate damage estimates suggest a strengthening of near-term action in cost-effective mitigation pathways (Schultes et al. 2021). Recently, the research community has begun to combine mitigation pathway analysis with *ex post* analysis of associated climate impacts and the benefits of mitigation (Drouet et al. 2021). Cost-effective pathways that tap into least cost abatement options globally without considering compensation schemes to equalise the mitigation burden between countries are not compatible with equity considerations. There is a large body of literature exploring international burden-sharing regimes to accompany globally cost-effective mitigation pathways (Tavoni et al. 2015; Pan et al. 2017; van den Berg et al. 2020).

Policy assumptions: Cost-effective mitigation scenarios assume that climate policies are globally uniform. There is a substantial literature

contrasting these benchmark cases with pathways derived under the assumption of regionally fragmented and heterogeneous mitigation policy regimes (Blanford et al. 2014b; Kriegler et al. 2015b, 2018b; Roelfsema et al. 2020; van Soest et al. 2021; Bauer et al. 2020b). For example, the Shared Policy Assumptions (Kriegler et al. 2014c) used in the SSP-RCP framework allow for some fragmentation of policy implementation, and many scenarios follow current policies or emission pledges until 2030 before implementing stringent policies (Riahi et al. 2015; Vrontisi et al. 2018; Roelfsema et al. 2020). Other studies assume a gradual strengthening of emissions pledges and regulatory measures converging to a globally harmonised mitigation regime slowly over time (Kriegler et al. 2018b; van Soest et al. 2021). With increasing announcements of mid-century strategies and the rise of net-zero CO₂ or GHG targets, global mitigation scenario analysis has begun to build in nationally-specific policy targets until mid-century (NGFS 2021).

Scenarios limiting warming to below 2°C phase in climate policies in all regions and sectors. Almost all converge to a harmonised global mitigation regime before the end of century (with the exception of Bauer et al. (2020b)). In practice, policies are often a mix of regulations, standards, or subsidies. Implementing these real-world policies can give different outcomes to optimal uniform carbon pricing (Mercure et al. 2019). Modelled carbon prices will generally be lower when other policies are implemented (Calvin et al. 2014a; Bertram et al. 2015). As countries implement more and a diverse set of policies, the need to further develop the policy assumptions in models is becoming apparent (Grant et al. 2020; O'Neill et al. 2020; Keppo et al. 2021).

Socio-economic drivers: Key socio-economic drivers of emission scenarios are assumptions on population and economic activity. There are other socio-economic assumptions, often included in underlying narratives (O'Neill et al. 2017), that strongly affect energy demand per capita or unit of GDP and dietary choices (Bauer et al. 2017; Popp et al. 2017; Grubler et al. 2018; van Vuuren et al. 2018). The SSPs are often used to help harmonise socio-economic assumptions, and further explore the scenario space. Many studies focus on the middle-of-the-road SSP2 as their default assumption, and many use SSP variations to explore the sensitivity of their results to socio-economic drivers (Marangoni et al. 2017; Riahi et al. 2017; Rogelj et al. 2017). While the SSPs help harmonisation, they are not unique and do not fully explore the scenario space (O'Neill et al. 2020). A wider range of narratives describing alternative worlds is also conceivable. The sustainability world (SSP1), for example, is a world with strong economic growth, but sustainability worlds with low growth or even elements of degrowth in developed countries could also be explored. Thus, standardisation of scenario narratives and drivers has advantages, but can also risk narrowing the scenario space that is explored by the literature. Consequently, many studies in the literature have adopted other socio-economic assumptions, for example with regard to population and GDP (Kriegler et al. 2016; Gillingham et al. 2018) and sustainable development trends (Soergel et al. 2021).

Technology availability and costs: Technology assumptions are a key component of IAMs, with some models representing hundreds

or thousands of technologies. Despite the importance of technology costs (Creutzig et al. 2017), there has been limited comparison of technology assumptions across models (Kriegler et al. 2015b; Krey et al. 2019). There is, however, a substantial literature on the sensitivity of mitigation scenarios to technology assumptions, including model comparisons (Kriegler et al. 2014a; Riahi et al. 2015), single-model sensitivity studies (McJeon et al. 2011; Krey and Riahi 2013; Giannousakis et al. 2021) and multi-model sensitivity studies (Bosetti et al. 2015). Not only are the initial technology costs important, but also how these costs evolve over time either exogenously or endogenously. Since IAMs have so many interacting technologies, assumptions on one technology can affect the deployment of another. For example, limits on solar energy expansion rates, or integration, may lead to higher levels of deployment for alternative technologies. Because of these interactions, it can be difficult to determine what factors affect deployment across a range of models.

Within these key scenario design choices, model choice cannot be ignored. Not all models can implement aspects of a scenario in the same way. Alternative target implementations are difficult for some model frameworks, and implementation issues also arise around technological change and policy implementation. Certain scenario designs may lock out certain modelling frameworks. These issues indicate the need for a diversity of scenario designs (Johansson et al. 2020) to ensure that model diversity can be fully exploited.

It is possible for many assumptions to be harmonised, depending on the research question. The SSPs were one project aimed at increasing harmonisation and comparability. It is also possible to harmonise emission data, technology assumptions, and policies (Giarola et al. 2021). While harmonisation facilitates greater comparability between studies, it also limits scenario and model diversity. The advantages and disadvantages of harmonisation need to be discussed for each model study.

A.III.II.2 Use of Scenarios in the Assessment

A.III.II.2.1 Use of Scenario Literature and Database

The WGIII assessment draws on the full literature on mitigation scenarios. To support the assessment, as many mitigation scenarios in the literature as possible were collected in a scenario database with harmonised output reporting (Annex III.II.3). The collection of mitigation pathways in a common database is motivated by a number of reasons: First, to establish comparability of quantitative scenario information in the literature which is often only sporadically available from tables and figures in peer-reviewed publications, reports and electronic supplementary information. Moreover, this information is often reported using different output variables and definitions requiring harmonisation. Second, to increase latitude of the assessment by establishing direct access to quantitative information underlying the scenario literature. Third, to improve transparency and reproducibility of the assessment by making the quantitative information underlying the scenario figures and tables shown in the report available to the readers of AR6. The use of such scenario databases in AR5 WGIII (Krey et al. 2014) and SR1.5 (Huppmann et al.

2018) proved its value for the assessment as well as for broad use of the scenario information by researchers and stakeholders. This is now being continued for AR6.

A.III.II.2.2 Treatment of Scenario Uncertainty

The calls for scenarios issued in preparation of this assessment report allowed the collection of a large ensemble of scenarios, coming from many modelling teams using various modelling frameworks in many different studies. Although a large ensemble of scenarios was gathered, it should be acknowledged that only a portion of the full uncertainty space is investigated, and that the distribution of the scenarios within the ensemble reflects the context of the studies the scenarios were developed in. This introduces 'biases' in the ensemble, for example, (i) the topics of the scenario studies collected in the database determine coverage of the scenario space, with large model-comparison studies putting large weight on selected topics over less explored topics explored by individual models, (ii) some models are more represented than others, (iii) only 'optimistic' models (i.e., models finding lower mitigation costs) reach the lowest mitigation targets (Tavoni and Tol 2010). Where appropriate, sampling bias was recognised in the assessment, but formal methods to reduce bias were not employed due to conceptual limitations.

Furthermore, although attempts have been made to elicit scenario likelihoods from expert knowledge (Christensen et al. 2018), scenarios are difficult to associate with probabilities as they typically describe a situation of deep uncertainty (Grübler and Nakicenovic 2001). This and the non-statistical nature of the scenario ensemble collected in the database do not allow a probabilistic interpretation of the distribution of output variables in the scenario database. Throughout the report, descriptive statistics are used to describe the spread of scenario outcomes across the scenarios ensemble. The ranges of results and the position of scenarios outcomes relative to some thresholds of interest are analysed. In some figures, the median of the distribution of results is plotted together with the interquartile range and possibly other percentiles (5th-10th-90th-95th) to facilitate the assessment of results, but these should not be interpreted in terms of likelihood of outcomes.

A.III.II.2.3 Feasibility of Mitigation Scenarios

In order to develop feasibility metrics of mitigation scenarios (Chapter 3, Section 3.8), the assessment relied on the multidimensional feasibility framework developed in Brutschin et al. (2021), considering five feasibility dimensions: (i) geophysical, (ii) technological, (iii) economic, (iv) institutional and (v) socio-cultural. For each dimension, a set of indicators was developed, capturing not only the scale but also the timing and the disruptiveness of transformative change (Kriegler et al. 2018b). All AR6 scenarios (C1–C3 climate categories) were categorised through this framework to quantify feasibility challenges by climate category, time, policy architecture and by feasibility dimension, summarised in Figure 3.43 (Chapter 3).

Scenarios were categorised into three levels of concerns: (i) low levels of concern where transformation is similar to the past or identified in the literature as feasible/plausible, (ii) medium levels of

Table 8 | Feasibility dimensions, associated indicators and thresholds for the onset of medium and high concerns about feasibility (Chapter 3.8).

		Indicators	Computation	Medium	High	Source
Geophysical		Biomass potential	Total primary energy generation from biomass in a given year	100 EJ yr ⁻¹	245 EJ yr ⁻¹	Frank et al. (2021); Creutzig et al. (2014)
		Wind potential	Total secondary energy generation from wind in a given year	830 EJ yr ⁻¹	2000 EJ yr ⁻¹	Deng et al. (2015); Eureka et al. (2017)
		Solar potential	Total primary energy generation from solar in a given year	1600 EJ yr ⁻¹	50 000 EJ yr ⁻¹	Rogner et al. (2012); Moomaw et al. (2011)
Economic		GDP loss	Decadal percentage difference in GDP in mitigation vs baseline scenario	5%	10%	Analogy to current COVID-19 spending Andrijevic et al. (2020c)
		Carbon price	Carbon price levels (NPV) and decadal increases	USD60	USD120 and 5×	Brutschin et al. (2021); OECD (2021)
		Energy investments	Ratio between investments in mitigation vs baseline in a given decade	1.2	1.5	McCollum et al. (2018)
		Stranded coal assets	Share of prematurely retired coal power generation in a given decade	20%	50%	Brutschin et al. (2021); Global Energy Monitor (2021)
Technological	Established	Wind/solar scale-up	Decadal percentage point increase in the wind/solar share in electricity generation	10 pp	20 pp	Brutschin et al. (2021); Wilson et al. (2020)
		Nuclear scale-up	Decadal percentage point increase in the nuclear share in electricity generation	5 pp	10 pp	Brutschin et al. (2021); Markard et al. (2020); Wilson et al. (2020)
	New Technologies	BECCS scale-up	Amount of CO ₂ captured in a given year	3 GtCO ₂ yr ⁻¹	7 GtCO ₂ yr ⁻¹	Warszawski et al. (2021)
		Fossil CCS scale-up	Amount of CO ₂ captured in a given year	3.8 GtCO ₂ yr ⁻¹	8.8 GtCO ₂ yr ⁻¹	Budinis et al. (2018)
		Biofuels in transport scale-up	Decadal percentage point increase in the share of biofuels in the final energy demand of the transport sector	5 pp	10 pp	Nogueira et al. (2020)
		Electricity in transport scale-up	Decadal percentage point increase in the share of electricity in the final energy demand of the transport sector	10 pp	15 pp	Muratori et al. (2021)
Socio-cultural		Total/transport/industry/residential energy demand decline	Decadal percentage decrease in demand	10 %	20 %	Grubler et al. (2018)
		Decline of livestock share in food demand	Decadal percentage decrease in the livestock share in total food demand	0.5 pp	1 pp	Grubler et al. (2018); Bajželj et al. (2014)
		Forest cover increase	Decadal percentage increase in forest cover	2 %	5 %	Brutschin et al. (2021)
		Pasture cover decrease	Decadal percentage decrease in pasture cover	5 %	10 %	Brutschin et al. (2021)
Institutional		Governance level and decarbonisation rate	Governance levels and per capita CO ₂ emission reductions over a decade	>0.6 and <20%	<0.6 and >20%	Brutschin et al. (2021); Andrijevic et al. (2020b)

concern that might be challenging but within reach, given certain enablers, (iii) high levels of concern representing unprecedented levels of transformation, attainable only under consistent enabling conditions. Indicator thresholds defining these three levels of concern were obtained from the available literature and developed with additional empirical literature. Table 8 summarises the main indicators used and the associated thresholds for medium and high levels of concern. Finally, we aggregated feasibility concerns for each dimension and each decade, employing the geometric mean, a non-compensatory method which limits the degree of substitutability between indicators, and used for example by the United Nations for the Human Development Index (HDI). Alternative aggregation scores such as the counting of scenarios exceeding the thresholds were also implemented.

A.III.II.2.4 Illustrative Mitigation Pathways

In the IPCC Special Report on Global Warming of 1.5°C (SR1.5), illustrative pathways (IPs) were used in addition to descriptions of the key characteristics of the full set of scenarios in the database to assess and communicate the results from the scenario literature. While the latter express the spread in scenario outcomes highlighting uncertain vs robust outcomes, IPs can be used to contrast different stories of mitigating climate change (Rogelj et al. 2018a).

Following the example of the SR1.5, IPs have also been selected for the AR6 of WGIII. In contrast to SR1.5, the selection needed to cover a larger range of climate outcomes while keeping the number of IPs limited. The selection focused on a range of critical themes that

emerged from the AR6 assessment: (i) the level of ambition of climate policy, (ii) the different mitigation strategies, (iii) timing of mitigation actions, and (iv) the combination of climate policy with sustainable development policies. The IPs consist of narratives (Table 9) as well as possible quantifications. The IPs are illustrative and denote implications of different societal choices for the development of future emissions and associated transformations of main GHG-emitting sectors. For Chapter 3, for each of the IPs a quantitative scenario was selected from the AR6 scenario database to have particular characteristics and from diverse modelling frameworks (Table 10).

In total, two reference pathways with warming above 2°C and five Illustrative Mitigation Pathways (IMPs) limiting warming in the 1.5–2°C range were selected. The first reference pathway follows

current policies as formulated around 2018 (Current Policies, CurPol) through to 2030 and then continues to follow a similar mitigation effort to 2100. The associated quantitative scenario (NGFS 2021) selected by Chapter 3 leads to about 3°C–4°C warming at the end of the century. The second reference pathway follows emission pledges to 2030 (NDCs) and then continues with moderate climate action over time (Moderate Action, ModAct).

The five IMPs are deep mitigation pathways with warming in the 1.5°C–2°C range. The first IMP pursues gradual strengthening beyond NDC ambition levels until 2030 and then acts to likely limit warming to 2°C (Climate Category C3) (IMP-GS) (van Soest et al. 2021) (Chapter 3.5.3). Three others follow different mitigation strategies focusing on low energy demand (IMP-LD) (Grubler et al. 2018),

Table 9 | Storylines for the two reference pathways and five Illustrative Mitigation Pathways (IMPs) limiting warming to 1.5°C–2°C considered in the report.

		General char.	Policy	Innovation	Energy	Land use, food biodiversity	Lifestyle
CurPol		Continuation of current policies and trends	Implementation of current climate policies and neglect of stated goals and objectives; grey COVID-19 recovery	Business as usual; slow progress in low-carbon technologies	Fossil fuels remain important; lock-in	Further expansion of western diets; further slow expansion of agriculture area	Demand will continue to grow; no significant changes in current habits
ModAct		NDCs in 2030 as announced in 2020, fragmented policy landscape; post-2030 action consistent with modest action until 2030	Strengthening of policies to implement NDCs; some further post-2030 strengthening and mixed COVID-19 recovery	Modest change compared to Cur-Pol	Mostly moving away from coal; growth of renewables; some lock-in in fossil investments	Afforestation/ reforestation policies as in NDCs	Modest change compared to Cur-Pol
IMP	Neg	Mitigation in all sectors includes a heavy reliance on carbon dioxide removal that results in net negative global GHG emissions	Successful international climate policy regime with a focus on a long-term temperature goal	Further development of CDR options	Heavy reliance on CDR in power sector and industry; CDR used to compensate fossil fuel emissions	Afforestation/ reforestation, BECCS, increased competition for land	Not critical – some induced via price increases
	Ren	Greater emphasis on renewables: rapid deployment and technology development of renewables; electrification	Successful international climate policy regime; policies and financial incentives favouring renewable energy	Rapid further development of innovative electricity technologies and policy regimes	Renewable energy; electrification; sector coupling; storage or power-to-X technologies; better interconnections		Service provisioning and demand changes to better adapt to high renewable energy supply
	LD	Efficient resource use as well as shifts in consumption patterns globally, leading to low demand for resources, while ensuring a high level of services and satisfying basic needs		Social innovation; efficiency; across all sectors	low demand for energy, while ensuring a high level of energy services and meeting energy needs; modal shifts in transport; rapid diffusion of best available technology in buildings and industry	Lower food and agricultural waste; less meat-intensive lifestyles	Service provisioning and demand changes; behavioural changes
	GS	less rapid introduction of mitigation measures followed by a subsequent gradual strengthening	Until 2030, primarily current NDCs are implemented and gradually strengthened moving gradually towards a strong, universal climate policy regime post-2030		Similar to IMP-Neg, but with some delay	Similar to IMP-Neg, but with some delay	
	SP	Shifting the global pathway towards sustainable development, including reduced inequality and deep GHG emissions reduction	SDG policies in addition to climate policy (poverty reduction; environmental protection)		low demand for energy, while ensuring a high level of energy services and meeting energy needs; renewable energy	Lower food and agricultural waste; less meat-intensive lifestyles; afforestation	Service provisioning and demand changes

Table 10 | Quantitative scenario selection to represent the two reference pathways and five Illustrative Mitigation Pathways warming to 1.5°C–2°C for the assessment in Chapter 3. These quantitative representations of the IMPs have also been taken up by a few other chapters where suitable. The warming profile of IMP-Neg peaks around 2060 and declines to below 1.5°C (50% likelihood) shortly after 2100. While technically classified as a C3, it exhibits the characteristics of C2 high overshoot pathways.

Acronym	Climate Category (II.3.2)	Model	Scenario name in the AR6 scenario database (III.II.3)	Reference
CurPol	C7	GCAM 5.3	NGFS2_Current Policies	NGFS (2021)
ModAct	C6	IMAGE 3.0	EN_INDCI2030_3000f	Riahi et al. (2021)
Illustrative Mitigation Pathways (IMPs)				
Neg	C2*	COFFEE 1.1	EN_NPI2020_400f_lowBECCS	Riahi et al. (2021)
Ren	C1	REMIND-MAGPIE 2.1-4.3	DeepElec_SSP2_HighRE_Budg900	Luderer et al. (2021)
LD	C1	MESSAGEix-GLOBIOM 1.0	LowEnergyDemand_1.3_IPCC	Grubler et al. (2018)
GS	C3	WITCH 5.0	CO_Bridge	van Soest et al. (2021)
SP	C1	REMIND-MAGPIE 2.1-4.2	SusDev_SDP-PkBudg1000	Soergel et al. (2021)
Sensitivity cases				
Neg-2.0	C3	AIM/CGE 2.2	EN_NPI2020_900f	Riahi et al. 2(021)
Ren-2.0	C3	MESSAGEix-GLOBIOM_GEI 1.0	SSP2_openres_lc_50	Guo et al. (2021)

renewable electricity (IMP-Ren) (Luderer et al. 2021) and large-scale deployment of carbon dioxide removal measures resulting in net negative CO₂ emissions in the second half of the century (IMP-Neg). The fifth IMP explicitly pursues a broad sustainable development agenda and follows SSP1 socio-economic assumptions (IMP-SP) (Soergel et al. 2021). IMP-LD, IMP-Ren and IMP-SP limit warming to 1.5°C (>50%) with no or limited overshoot (C1), while IMP-Neg has a higher overshoot and only returns to nearly 1.5°C (50% chance) by 2100 (close to C2). In addition, two sensitivity cases for IMP-Ren and IMP-Neg are considered that limit warming to 2°C (>67%) (C3) rather than pursuing limiting warming to 1.5°C.

The IMPs are used in different parts of the report. We just mention some examples here. In Chapter 3, they are used to illustrate key differences between the mitigation strategies, for instance in terms of timing and sectoral action. In Chapter 6, Box 6.9 discusses the consequences for energy systems. Chapter 7 discusses some of the land-use consequences. In Chapter 8, the implications of the IMPs are further explored for urban systems where the elements of energy, innovation, policy, land use and lifestyle interact (Chapter 8, Sections 8.3 and 8.4). In Chapter 10, the consequences of different mitigation strategies for mobility are highlighted in different figures. The IMPs are discussed further in Chapter 1, Section 1.3; Chapter 3, Section 3.2; and the respective sector chapters.

A.III.II.2.5 Scenario Approaches to Connect WGIII with the WGI and WGII assessments

A.III.II.2.5.1 Assessment of WGIII Scenarios Building on WGI Physical Climate Knowledge

A transparent assessment pipeline has been set up across WGI and WGIII to ensure integration of the WGI assessment in the climate assessment of emission scenarios in WGIII. This pipeline consists of a step where emissions scenarios are harmonised with historical emissions (harmonisation), a step in which species not reported by an IAM are filled in (infilling), and a step in which the emission evolutions are assessed with three climate model emulators

(Annex III.I.8) calibrated to the WGI assessment. These three steps ensure a consistent and comparable assessment of the climate response across emission scenarios from the literature.

Harmonisation: IAMs may use different historical datasets, and emission scenarios submitted to the AR6 WGIII scenario database (Annex III.II.3) are therefore harmonised against a common source of historical emissions. To be consistent with WGI, we use the same historical emissions that were used for CMIP6 and RCMIP (Gidden et al. 2018; Nicholls et al. 2020b). This dataset comprises many different emission harmonisation sources (Velders et al. 2015; Gütschow et al. 2016; Le Quéré et al. 2016; van Marle et al. 2017; Meinshausen et al. 2017; Hoesly et al. 2018), including estimates of CO₂ emissions from agriculture, forestry, and land-use change (mainly CEDS, (Hoesly et al. 2018)) which are on the lower end of historical observation uncertainty as assessed in Chapter 2. The harmonisation is performed so that different climate futures resulting from two different scenarios are a result of different future emission evolutions within the scenarios, not due to different historical definitions and starting points. Sectoral CO₂ emissions from energy and industrial processes and CO₂ from agriculture, forestry, and land-use change were harmonised separately. All other emissions species are harmonised based on the total reported emissions per species. For CO₂ from energy and industrial processes we use a ratio-based method with convergence in 2080, in line with CMIP6 (Gidden et al. 2018, 2019). For CO₂ from agriculture, forestry, and land-use change and other emissions species with high historical interannual variability, we use an offset method with convergence target 2150, to avoid strong harmonisation effects resulting from uncertainties in historical observations. For all remaining fluorinated gases (F-gases), constant ratio harmonisation is used. For all other emissions species, we use the default settings of Gidden et al. (2018, 2019a).

Infilling missing species: Infilling ensures that scenarios include all relevant anthropogenic emissions. This reduces the risk of a biased climate assessment and is important because not all IAMs report all climatically active emission species. Infilling was only performed for scenarios where models provided native reporting of energy

and industrial process CO₂, land use CO₂, CH₄, and N₂O emissions to avoid infilling gases that have large individual radiative forcing contributions and cannot be infilled with high confidence. Models that did not meet this minimum reporting requirement were not included in the climate assessment. Infilling is performed following the methods and guidelines in Lamboll et al. (2020). Missing species are infilled based on the relationship with CO₂ from energy and industrial processes as found in the harmonised set of all scenarios reported to the WGIII scenario database that pass the vetting requirements. To ensure high stability to small changes, we apply a Quantile Rolling Window method (Lamboll et al. 2020) for aerosol precursor emissions, volatile organic compounds and greenhouse gases other than F-gases, based on the quantile of the reported CO₂ from energy and industrial processes in the database at each time point. F-gases and other gases with small radiative forcing are infilled based on a pathway with lowest root mean squared difference, allowing for consistency in spite of limited independently modelled pathways in the database.

WGI-calibrated emulators: Using expert judgement, emulators that reproduce the best estimates and uncertainties of the majority of AR6 WGI assessed metrics are recommended for scenario classification use by WGIII (see WGI Cross-Chapter Box 7.1). MAGICC (v7) was used for the main scenario classification, with FaIR (v1.6.2) being used to provide additional uncertainty ranges on reported statistics to capture climate model uncertainty. The WGI emulators' probabilistic parameter ensembles are derived such that they match a range of key climate metrics assessed by WGI and the extent to which agreement is achieved is evaluated (WGI Cross-Chapter Box 7.1). Of particular importance to this evaluation is the verification against the WGI temperature assessment of the five scenarios assessed in Chapter 4 of WGI (SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5). The inclusion of the temperature assessment as a benchmark for the emulators provides the strongest verification that WGIII's scenario classification reflects the WGI assessment. The comprehensive nature of the evaluation is a clear improvement on previous reports and ensures that multiple components of the emulators, from their climate response to effective radiative forcing through to their carbon cycles, have been examined before they are deemed fit for use by WGIII.

Scenario climate assessment: For the WGIII scenario climate assessment, emulators are run hundreds to thousands of times per scenario, sampling from an emulator-specific probabilistic parameter set, which incorporates carbon cycle and climate system uncertainty in line with the WGI assessment (WGI Cross-Chapter Box 7.1). Percentiles for different output variables provide information about the spread in individual variables for a given scenario, but the set of variables for a given percentile do not form an internally consistent climate change projection. Instead, joint distributions of these parameter sets are employed by the calibrated emulators. Consistent climate change projections are represented by individual ensemble member runs and the whole ensemble of these individual member runs. To facilitate analysis, multiple percentiles of these large (hundred to thousand member) ensemble distributions of projected climate variables are provided in the AR6 scenario database. The emulators provide an assessment of global surface air temperature (GSAT) response to emission scenarios and its key characteristics like peak warming and

year of peak warming, ocean heat uptake, atmospheric CO₂, CH₄ and N₂O concentrations and effective radiative forcing from a range of species including CO₂, CH₄, N₂O and aerosols for each emissions scenario, as well as an estimate of CO₂ and non-CO₂ contributions to the temperature increase. The climate emulator's GSAT projections are normalised to match the WGI Chapter 2 assessed total warming between 1850–1900 and 1995–2014 of 0.85°C.

The GSAT projections from the emulator runs are used for classifying those emissions scenarios in the AR6 database that passed the initial vetting and allowed a robust climate assessment. MAGICC (v7) was selected as emulator for the climate classification of scenarios, as it happens to be slightly warmer than the other considered climate emulator, particularly for the higher and long-term warming scenarios – reflecting long-term warming in line with Earth system models (ESMs) (WGI Cross-Chapter Box 7.1). This means that scenarios identified to stay below a given warming limit with a given probability by MAGICC will in general be identified to have this property by the other emulator as well. There is the possibility that the other emulator would classify a scenario in a lower warming class based on their slightly cooler emulation of the temperature response. Unlike during the assessment of the SR1.5 database in the IPCC SR1.5 report, the updated versions of FaIR and MAGICC are however very close, providing robustness to the climate assessment. MAGICC and FaIR were both used to assess the overall uncertainty in the warming response for a single scenario or a set of scenarios, including both parametric and model uncertainty. Specifically, the 5th to 95th percentile range across the two emulators is calculated, characterising the joint climate uncertainty range of the two models.

Carbon budgets in WGI and WGIII: The remaining carbon budget corresponding to a certain level of future warming depends on non-CO₂ emissions of modelled pathways. Box 3.4 in Chapter 3 highlighted this key uncertainty in estimating carbon budgets. In this section (Figure 5), we put this into the context of the dependence of carbon budgets on two aspects of the non-CO₂ warming contribution: (i) assumptions on historical non-CO₂ emissions and how they can impact future non-CO₂ warming estimates relative to a recent reference period (2010–2019) (Panel a) and (ii) the scenario set underlying estimates of non-CO₂ warming at the time of reaching net zero CO₂ (Panel b). Both aspects affect the estimated remaining carbon budget by changing the non-CO₂ warming contribution from the base year to the time of reaching net zero CO₂. MAGICC7 is used in WGI in conjunction with different input files for the historical warming. For the reported remaining carbon budget estimates (WGI CB) WGI used the non-CO₂ warming contributions from MAGICC7 in line with Meinshausen et al. (2020) and in line with the CMIP6 GHG concentration projections, while the WGI emulator setup in line with WGI Cross-Chapter Box 7.1 was used for the WGIII climate assessment. The WGIII assessment uses MAGICC7 in line with Nicholls et al. (2021) in line with the emission harmonisation process employed in WGIII (see above). The difference in historical assumptions changes the estimated non-CO₂ contribution by up to about 0.05°C for the lower temperature levels, or slightly more than 10% of the warming until 1.5°C relative to 2010–2019. For peak warming around 2°C relative to pre-industrial levels (about 0.97°C warming relative to 2010–2019 in Figure 5 plots), the difference is

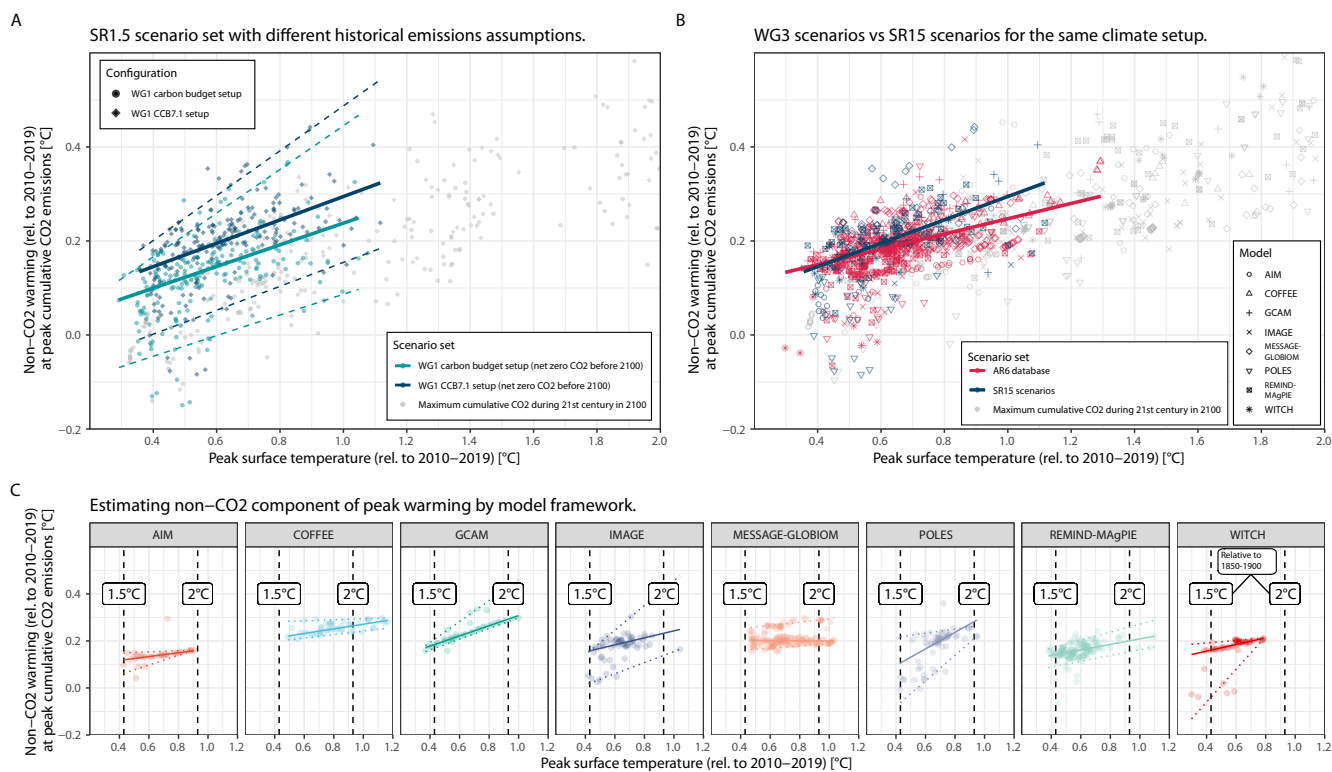

Figure 5 | Comparison of non-CO₂ warming relevant for the derivation of cumulative carbon budgets – and its sensitivity to (a) assumptions on historical emissions and (b) the set of investigated scenarios (right). Panel (c) shows how the relationship across scenarios between peak surface temperature and non-CO₂ warming and peak cumulative CO₂ is different for modelling frameworks. All dashed regression lines are at the 5th and 95th percentiles, solid lines are a regression at the median.

All panels depict non-CO₂ warming in relation to 2010–2019 at the time of peak cumulative CO₂, using MAGICC7. Scenarios that reach net-zero CO₂ this century are coloured, with dots in grey indicating scenarios that do not reach net-zero CO₂ but still remain below 2°C median peak warming relative to 2010–2019 levels in this century. The scenario set ‘AR6 database’ in (b) includes only scenarios of those model frameworks that are shown in panel (c) which have a detailed land-use model and enough scenarios to imply a relationship.

Panel (a) The WGI remaining carbon budget takes into account the non-CO₂ warming in dependence of peak surface temperatures via a regression line approach (lighter blue-coloured solid line). For the same scenario set, with historical emissions assumptions as used in Cross-Chapter Box 7.1 (darker blue-coloured solid line), a relationship is found with a difference of approximately 0.05°C.

Panel (b) The WGIII database of scenarios tends to imply very similar non-CO₂ warming at peak cumulative CO₂ to the SR15 scenario database, especially around 1.5°C above pre-industrial (0.43°C above 2010–2019 levels), though with slightly lower non-CO₂ warming for higher peak temperatures.

Panel (c) Regressions at the 5th, 50th, and 95th percentiles indicate a model framework footprint affecting the relationship between peak warming and non-CO₂ warming at peak cumulative CO₂.

offset by the difference arising from using either the SR1.5 or AR6 scenario databases (see panel (b) in Figure 5).

(e.g., dietary change scenarios) can have strong effects on estimated carbon budgets for staying below 1.5°C.

Estimates of the remaining carbon budget that take into account non-CO₂ uncertainty are not only dependent on historical assumptions, but also on future non-CO₂ scenario characteristics, which are different across the various scenarios in the AR6 database. In panel (b) of Figure 5, we show how the SR15 database of scenarios, which was used to inform the WGI remaining carbon budget, differs from the larger set considered in the WGIII report (both using MAGICC7 using input files in line with Nicholls et al. (2021)). Overall, there is limited difference in the covered range of non-CO₂ warming at different peak surface temperature levels, leading to no clear change in estimated carbon budgets compared to SR1.5 based on the full scenario database. However, as discussed in Cross-Working Group Box 1 in Chapter 3, and shown in panel (c) of Figure 5, mitigation strategies expressed by both the IAM footprint and scenario design

A.III.II.2.5.2 Relating the WGII and WGIII Assessments by use of Warming Levels

WGII sets out common climate dimensions to help contextualise and facilitate consistent communication of impacts and synthesis across WGII, as well as to facilitate WGI and WGII integration, with the dimensions adopted when helpful and possible across WGII (AR6 WGII Cross-Chapter Box 1.1). ‘Common climate dimensions’ are defined as common global warming levels (GWs), time periods, and levels of other variables as needed by WGII authors (see below for a list of variables associated with these dimensions). Projected ranges for associated climate variables were derived from the AR6 WGI report and supporting resources and help contextualise and inform the projection of potential future climate impacts and key risks. The information enables the mapping of climate variable levels to climate

projections by WGI (AR6 WGI Table SPM.1) and vice versa, with ranges of results provided to characterise the physical uncertainties relevant to assessing climate impacts risk. Common socio-economic dimensions are not adopted in WGII due to a desire to draw on the full literature, inform the broad ranges of relevant possibilities (climate, development, adaptation, mitigation), and be flexible. The impacts literature is wide-ranging and diverse, with a fraction based on global socio-economic scenarios. WGII's approach allows chapters and cross-chapter boxes to assess how impacts and ranges depend on socio-economic factors affecting exposure, vulnerability, and adaptation independently, as appropriate for their literature. For example, WGII Chapter 16 assesses how Representative Key Risks vary under low vs high exposure/vulnerability conditions by drawing on impact literature based on Shared Socio-economic Pathways (SSPs). In general, WGII chapters, when possible and conducive with their literature, used GWLs or climate projections based on Representative Concentration Pathways or SSPs to communicate information and facilitate integration and synthesis, with impacts results characterised according to other drivers when possible and relevant, such as socio-economic conditions.

In the context of common climate dimensions, WGII considers common projected GWL ranges by time period, the timing for when GWLs might be reached, and projected continental-level result ranges for select temperature and precipitation variables by GWL (average and extremes), as well as sea surface temperature changes by GWL and ocean biome. Where available, WGII considers the assessed WGI ranges as well as the raw CMIP5 and CMIP6 climate change projections (ranges and individual projections) from Earth system models (Hauser et al. 2019). With WGII's climate impacts literature based primarily on climate projections available at the time of AR5 (CMIP5) and earlier, or assumed temperature levels, it was important to be able to map climate variable levels to climate projections of different vintages and vice versa. WGII's common GWLs are based on AR6 WGI's proposed 'Tier 1' dimensions of integration range – 1.5, 2.0, 3.0, and 4.0°C (relative to the 1850 to 1900 period), which are simply proposed common GWLs to facilitate integration across and within WGs (WGI Chapter 1). Within WGII, GWLs facilitate comparison of climate states across climate change projections, assessment of the full impacts literature, and cross-chapter comparison. Across AR6, GWLs facilitate integration across Working Groups of climate change projections, climate change risks, adaptation opportunities, and mitigation.

For facilitating integration with WGIII, GWLs need to be related to WGIII's classification of mitigation efforts by temperature outcome. WGII's Chapter 3 groups full century emissions projections resulting from a large set of assessed mitigation scenarios into temperature classes (Chapter 3, Sections 3.2 and 3.3, Annex III.II.2.5.1, and Annex III.II.3.2.1). Scenarios are classified by median peak global mean temperature increase since 1850–1900 in the bands <2°C, 2°C–2.5°C, 2.5°C–3°C, 3°C–4°C, and >4°C, with the range below 2°C broken out in greater detail using estimates of warming levels at peak and in 2100 for which the warming response is projected to be likely higher (33th percentile), as likely higher as lower (median), and likely lower (67th percentile) (Chapter 3, Section 3.2 and Annex III.II.3.2.1). WGII's common GWLs

and WGIII's global warming scenario classes are relatable but differ in several important ways. While GWLs represent temperature change that occurs at some point in time, emissions scenarios in a temperature class result in an evolving warming response over time. The emissions scenario warming also has a likelihood attached to the warming level at any point in time, that is, actual warming outcomes can be lower or higher than median warming projections within the range of the estimated uncertainty. Thus, multiple WGII results across GWLs will be relevant to any particular WGIII emissions pathway, including at the peak temperature level.

However, socio-economic conditions are an important factor defining both impacts exposure, vulnerability, and adaptation, as well as mitigation opportunity and costs, that needs special considerations. The WGIII scenario assessment is using additional classifications relating to, inter alia, near-term policy developments, technology availability, energy demand, population and economic growth (Chapter 3, Section 3.3 and Annex III.II.3.2.2), and a set of illustrative mitigation pathways with varying socio-techno-economic assumptions (Annex III.II.2.4, Chapter 3, Section 3.2). Synthesising WGII assessments of climate change impacts and WGIII assessments of climate change mitigation efforts for similar GWLs/global warming scenario classes would have to address how socio-techno-economic conditions affect impacts, adaptation, and mitigation outcomes. Furthermore, a synthesis of mitigation costs and mitigation benefits in terms of avoided climate change impacts would require a framework that ensures consistency in socio-economic development assumptions and emissions and adaptation dynamics and allows for consideration of benefits and costs along the entire pathway (O'Neill et al. 2020) (Cross-Working Group Box 1 in Chapter 3).

A.III.II.3 WGIII AR6 Scenario Database

[Note: The scenario numbers documented in this section refer to all scenarios that were submitted and not retracted by the literature acceptance deadline of 11 October 2021, and that fulfilled the requirement of being supported by an eligible literature source. Not all those scenarios were used in the assessment, for example some did not pass the vetting process as documented in II.3.1.]

As for previous IPCC reports of Working Group III, including the Special Report on Global Warming of 1.5°C (SR1.5) (Huppmann et al. 2018; Rogelj et al. 2018a) and the Fifth Assessment Report (AR5) (Clarke et al. 2014; Krey et al. 2014), quantitative information on mitigation pathways is collected in a dedicated AR6 scenario database⁸ to underpin the assessment.

By the time of the AR6 literature acceptance deadline of IPCC WGIII (11 October 2021) the AR6 scenario database comprised 191 unique modelling frameworks (including different versions and country setups) from 95+ model families – of which 98 were globally comprehensive, 71 national or multi-regional, and 20 sectoral models – with in total 3,131 scenarios, summarised in Tables 11–17

⁸ <https://data.ece.iiasa.ac.at/ar6/>.

(global mitigation pathways), Table 18 (national and regional mitigation pathways) and Table 19 (sector transition pathways).

A.III.II.3.1 Process of Scenario Collection and Vetting

To facilitate the AR6 assessment, modelling teams were invited to submit their available emissions scenarios to a web-based database hosted by the International Institute for Applied Systems Analysis (IIASA).⁹ The co-chairs of Working Group III as well as a range of scientific institutions, including the Integrated Assessment Modelling Consortium (IAMC), University of Cape Town and the Centre International de Recherche sur l'Environnement et le Développement (CIRED), supported the open call for scenarios which was subdivided into four dedicated calls:

- a call for global long-term scenarios to underpin the assessment in Chapter 3 as well as facilitating integration with sectoral Chapters 6, 7, 8, 9, 10 and 11,
- a call for short- to medium-term scenarios at the national and regional scales underpinning the assessment in Chapter 4, and
- a call for building-focused scenarios to inform the assessment in Chapter 9, and
- a call for transport-focused scenarios to inform the assessment in Chapter 10.

A common data reporting template with a defined variable structure was used and all teams were required to register and submit detailed model and scenario metadata. Scenarios were required to come from a formal quantitative model and the scenarios must be published in accordance with IPCC literature requirements. The calls for scenarios

were open for a period of 22 months (September 2019 to July 2021), with updates possible until October 2021 in line with the literature acceptance deadline. The data submission process included various quality control procedures to increase accuracy and consistency in reporting. Additional categorisation and processing of metadata over the full database provided a wide range of indicators and categories that were made centrally available to authors of the report to enhance consistency of the assessment, such as: climate, policy and technology categories; characteristics about emissions, energy, socio-economics and carbon sequestration; metadata such as literature references, model documentation and related projects.

For all scenarios reporting global data, a vetting process was undertaken to ensure that key indicators were within reasonable ranges for the baseline period – primarily for indicators relating to emissions and the energy sector (Table 11). As part of the submission process, model teams were contacted individually with information on the vetting outcome with regard to their submitted scenarios, giving them the opportunity to verify the reporting of their data. Checks on technology-specific variables for nuclear, solar and wind energy, and CCS, screen not only for accuracy with respect to recent developments, but also indicate reporting errors relating to different primary energy accounting methods. While the criteria ranges appear to be large, the focus of these scenarios is the medium to long term and there is also uncertainty in the historical values. For vetting of the Illustrative Mitigation Pathways, the same criteria were used, albeit with narrower ranges (Table 11). Selected future values were also vetted and the result of the vetting reported to authors, but not used as exclusion criterion. Where possible the latest values available were used, generally 2019, and if necessary extrapolated to 2020 as most

Table 11 | Summary of the vetting criteria and ranges applied to the global scenarios for the climate assessment and preliminary screening for Illustrative Mitigation Pathways.

	Reference value	Range (IP range)	Pass	Fail	Not reported
Historical emissions (sources: EDGAR v6 IPCC and CEDS, 2019 values)					
CO ₂ total (EIP + AFOLU) emissions	44,251 MtCO ₂ yr ⁻¹	±40% (±20%)	1848	23	395
CO ₂ EIP emissions	37,646 MtCO ₂ yr ⁻¹	±20% (±10%)	2162	55	49
CH ₄ emissions	379 MtCH ₄ yr ⁻¹	±20% (±20%)	1651	139	476
CO ₂ emissions EIP 2010–2020 % change	–	+0 to +50%	1742	74	450
CCS from energy 2020	–	0-250 (100) MtCO ₂ yr ⁻¹	1624	77	565
Historical energy production (sources: IEA 2019; IRENA; BP; EMBERS; trends extrapolated to 2020)					
Primary energy (2020, IEA)	578 EJ	±20% (±10%)	1813	73	380
Electricity: nuclear (2020, IEA)	9.77 EJ	±30% (±20%)	1603	266	397
Electricity: solar and wind (2020, IEA, IRENA, BP, EMBERS).	8.51 EJ	±50% (±25%)	1459	377	430
Overall			1686	580	–
Future criteria (not used for exclusion in climate assessment but flagged to authors as potentially problematic)					
No net negative CO ₂ emissions before 2030	CO ₂ total in 2030 >0		1867	4	395
CCS from energy in 2030	<2000 MtCO ₂ yr ⁻¹		1518	183	565
Electricity from nuclear in 2030	<20 EJ yr ⁻¹		1595	274	397
CH ₄ emissions in 2040	100–1000 MtCH ₄ yr ⁻¹		1775	15	476

Rows do not sum to the same total of scenarios as not all scenarios reported all variables. EIP stands for energy and industrial process emissions.

⁹ <https://data.ene.iiasa.ac.at/ar6/#/about>.

models report only at five- to 10-year intervals. 2020 as reported in most scenarios collected in the database does not include the impact of the COVID-19 pandemic.

Almost three-quarters of submitted global scenarios passed the vetting. The remaining quarter comprised a fraction of scenarios that were rolled over from the SR1.5 database, and were no longer up to date with recent developments (excluding the COVID-19 shock). This included scenarios that started stringent mitigation action already in 2015. Other scenarios were expected to deviate from historical trends due to their diagnostic design. All historical criteria for reported variables needed to be met in order to pass the vetting.

2266 global scenarios were submitted to the scenario database that fulfilled a minimum requirement of reporting at least one global emission or energy variable covering multiple sectors. 1686 global scenarios passed the vetting criteria described in Table 11. These scenarios were subsequently flagged as meeting minimum quality standards for use in long-term scenarios assessment. Additional

criteria for inclusion in the Chapter 3 climate assessment are described in Annex III.II.3.2.1.

A.III.II.3.2 Global Pathways

Scenarios were submitted by both individual studies and model inter-comparisons. The main model inter-comparisons submitting scenarios are shown in Table 12. Model inter-comparisons have a shared experimental design and assess research questions across different modelling platforms to enable more structured and systematic assessments. The model comparison projects thus help to understand the robustness of the insights.

The number of submitted scenarios varies considerably by study, for example from 10 to almost 600 scenarios for the model inter-comparison studies (Table 12). The number of scenarios also varies substantially by model (Table 15), highlighting the fact that the global scenario set collected in the AR6 scenario database is not a statistical sample (Section II.2.2).

Table 12 | Model inter-comparison studies that submitted global scenarios to the AR6 scenario database and for which at least one scenario passed the vetting. Scenario counts refer to all scenarios submitted by a study (in brackets), those that passed vetting (centre) and those that passed the vetting and received a climate assessment (left).

A.III.II.3.2.1 Climate Classification of Global Pathways

The global scenarios underpinning the assessment in Chapter 3 have been classified, to the degree possible, by their warming outcome. The definition of the climate categories and the distribution of scenarios in the database across these categories is shown in Table 14 (Chapter 3, Section 3.2). The first four of these categories correspond to the ones used in the IPCC SR1.5 (Rogelj et al. 2018a) while the latter four have been added as part of the AR6 to capture a broader range of warming outcomes.

For inclusion in the climate assessment, in addition to passing the vetting (Section II.3.1), scenarios needed to run until the end of century and report as a minimum CO₂ (total and for energy and industrial processes (EIP)), CH₄ and N₂O emissions to 2100. Where CO₂ for AFOLU was not reported, the difference between total and EIP in 2020 must be greater than 500 MtCO₂. Of the total 2266 global scenarios submitted, 1574 could be assessed in terms of their associated climate response, and 1202 of those passed the vetting process.

Table 14 | Classification of global pathways into warming levels using MAGICC (Chapter 3, Section 3.2).

Description	Definition	Scenarios	
		Passed vetting	All
C1: Limit warming to 1.5°C (>50%) with no or limited overshoot	Reach or exceed 1.5°C during the 21st century with a likelihood of ≤67%, and limit warming to 1.5°C in 2100 with a likelihood >50%. Limited overshoot refers to exceeding 1.5°C by up to about 0.1°C and for up to several decades.	97	160
C2: Return warming to 1.5°C (>50%) after a high overshoot	Exceed warming of 1.5°C during the 21st century with a likelihood of >67%, and limit warming to 1.5°C in 2100 with a likelihood of >50%. High overshoot refers to temporarily exceeding 1.5°C global warming by 0.1°C–0.3°C for up to several decades.	133	170
C3: Limit warming to 2°C (>67%)	Limit peak warming to 2°C throughout the 21st century with a likelihood of >67%.	311	374
C4: Limit warming to 2°C (>50%)	Limit peak warming to 2°C throughout the 21st century with a likelihood of >50%.	159	213
C5: Limit warming to 2.5°C (>50%)	Limit peak warming to 2.5°C throughout the 21st century with a likelihood of >50%.	212	258
C6: Limit warming to 3°C (>50%)	Limit peak warming to 3°C throughout the 21st century with a likelihood of >50%.	97	129
C7: Limit warming to 4°C (>50%)	Limit peak warming to 4°C throughout the 21st century with a likelihood of >50%.	164	230
C8: Exceed warming of 4°C (≥50%)	Exceed warming of 4°C during the 21st century with a likelihood of ≥50%.	29	40
No climate assessment	Scenario time horizon <2100; insufficient emissions species reported.	484	692
	Total:	1686	2266

Table 15 | Global scenarios by modelling framework and climate category. Table includes number of scenarios that passed all vetting checks and number of all scenarios that received a climate categorisation (in brackets, including those not passing vetting). Unique model versions have been grouped into modelling frameworks for presentation in this table.¹² For a full list of unique model versions, please see the AR6 scenario database.

Model group	C1: Limit to 1.5°C (>50%) with no or limited OS	C2: Return to 1.5°C (>50%) after high OS	C3: Limit to 2°C (>67%)	C4: Limit to 2°C (>50%)	C5: Limit to 2.5°C (>50%)	C6: Limit to 3.0°C (>50%)	C7: Limit to 4.0°C (>50%)	C8: Exceed 4.0°C (≥50%)	No climate assessment	Total with climate categorisation

¹³ Scenario numbers by modelling framework combine submissions from different model versions of the same model (indicated by version number or project name in the AR6 scenario database).

Changes in climate classification of scenarios since SR1.5: Since the definition of warming classes was unchanged from SR1.5 for the lower range of scenarios limiting warming to 2°C or lower, changes in overall emissions characteristics of scenarios in these classes from SR1.5 to AR6 would need to come from the substantially larger ensemble of deep mitigation scenarios collected in the AR6 database compared to the SR1.5 database and from updates in the methodology of the climate assessment. Updates since SR1.5 include the methodology for infilling and harmonisation and the use of an updated climate emulator (MAGICC v7) to provide consistency with AR6 WGI assessment (Annex III.II.2.5.1). Out of the full set of SR1.5, 57% of the 411 scenarios that were represented with global temperature assessments in SR1.5 also have been assessed in AR6. Some SR1.5 scenarios could not be taken on board since they are outdated (too early emissions reductions) and failed the vetting or do not provide sufficient information/data to be included in AR6.

Comparison between SR1.5 and AR6 scenarios and associated climate responses are shown in Figure 6, bottom panel. We show that changes in the climate assessment pipeline are minor compared to climate model uncertainty ranges in WGI (in the order of 0.1°C), but show considerable variation due to different scenario characteristics. The updated harmonisation and infilling together have a small cooling effect compared to raw modelled emissions for the subset of 95 scenarios in C1, C2, and C3 that also were assessed in SR15 (SR1.5 Chapter 2, Table 2.4). This is due to both applying more advanced harmonisation methods consistent with the CMIP6 harmonisation used for WGI, and changing the historical harmonisation year from 2010 to 2015. Together with the update in the climate emulator, we find that the total AR6 assessment is remarkably consistent with SR1.5, albeit slightly cooler (in the order of 0.05°C at peak temperature, 0.1°C in 2100).

The lowest temperature category (C1, limiting warming to 1.5°C with no or low overshoot) used for classifying the most ambitious climate mitigation pathways in the literature, indicates that emissions are on average higher in AR6 in the near term (e.g., 2030) and the time of net-zero CO₂ is later by about five years compared to SR1.5 (Figure 6, middle panel). These differences can in part be ascribed to the fact that historical emissions in scenarios, especially among those that passed the vetting, have risen since SR1.5 in line with inventories. This increase has moved the attainable near-term emissions reductions upwards. As a result, the scenarios in the lowest category have also a lower probability of staying below 1.5°C peak warming. Using the WGI emulators, we find that the median probability of staying below 1.5°C in the lowest category (C1) has dropped from about 46% in the SR1.5 scenarios to 38% among the AR6 scenarios. Note that the likelihood of the SR1.5 scenarios limiting warming to 1.5°C with no or limited overshoot has changed from 41% in SR1.5 to 46% in AR6 due to the updated climate assessment using the WGI AR6 climate emulator. Within C1, the vast majority of scenarios that were submitted to AR6 but were not assessed in SR1.5 have median peak temperatures close to 1.6°C. The AR6 scenarios in the lowest category show higher emissions and have a lower chance of keeping warming below 1.5°C, as indicated by the panels showing the distribution of peak warming and exceedance probability in AR6 vs SR1.5, with for instance C1 median peak temperature warming going

from 1.55°C in SR1.5 (1.52°C if reassessed with AR6 assessment pipeline) to 1.58°C in AR6.

A.III.II.3.2.2 Policy Classification of Global Scenarios

Global scenarios were also classified based on their assumptions regarding climate policy. This information can be deduced from study protocols or the description of scenario designs in the published literature. It has also been elicited as meta-information for scenarios that were submitted to the AR6 database. There are multiple purposes for a policy classification, including controlling for the level of near-term action (Chapter 3, Section 3.5) and estimating costs and other differences between two policy classes (Chapter 3, Section 3.6). Policy classes can be combined with climate classes, for example to identify scenarios that follow the NDC until 2030 and limit warming to 2°C (>67%).

Table 17 presents the policy classification that was chosen for this assessment and the distribution of scenarios across the policy classes. There is a top-level distinction between diagnostic scenarios, scenarios from cost-benefit analyses, scenarios without globally coordinated action, scenarios with immediate such action, and hybrid scenarios that move to globally coordinated action after a period of diverse and uncoordinated national action. On the second hierarchy level, scenarios are classified along distinctive features of scenarios in each class. Scenarios without globally coordinated action are often used as reference scenarios and come as baselines without climate policy efforts, as an extrapolation of current policy trends or as implementation and extrapolation of NDCs (Grant et al. 2020). Scenarios that act immediately to limit warming to some level can be distinguished by whether or not they include transfers to reflect equity considerations (Tavoni et al. 2015; Bauer et al. 2020c; van den Berg et al. 2020) or by whether or not they assume additional policies augmenting a global carbon price (Soergel et al. 2021). Scenarios that delay globally coordinated action until 2030 can differ in their assumptions about the level of near-term action (Roelfsema et al. 2020; van Soest et al. 2021).

To identify the policy classification of each global scenario in the AR6 database, classes are first assigned via text pattern matching on all the metadata collected when submitting the scenarios to the database. The algorithm first looks for keywords and text patterns to establish whether a scenario represents a global, fragmented, diagnostic or CBA policy setup. Then it looks for evidence on the presence of specific regional policies, delayed actions and transfers of permits. Eventually the different pieces of evidence are harmonised into a single policy categorisation decision. The process has been calibrated on the best-known scenarios belonging to the larger model intercomparison projects, and fine-tuned on the other scenarios via further validation against the related literature, consistency checks on reported emission and carbon price trajectories, exchanges with modellers and supervision by the involved IPCC authors. If the information available is enough to identify a policy category number but not sufficient for a subcategory, then only the number is retained (e.g., P2 instead of P2a/b/c). A suffix added after P0 further qualifies a diagnostic scenario as one of the other policy categories.

Table 17 | Policy classification of global scenarios. If the total for a class exceeds the sum of the subclasses, there are scenarios in the class that could not be assigned to a subclass.

Class	Definition	Number of scenarios		
		Passed vetting, with climate assessment	Passed vetting	All
P0	Diagnostic scenario	73	99	138
P1	No globally coordinated climate policy and either	207	500	632
P1a	– no climate mitigation efforts	72	124	179
P1b	– current national mitigation efforts	51	59	72
P1c	– NDCs	56	160	184
P1d	– other policy assumptions	24	153	189
P2	Globally coordinated climate policies with immediate (i.e., before 2030) action and	579	634	992
P2a	– without any transfer of emission permits	403	435	610
P2b	– with transfers	70	70	143
P2c	– with additional policy assumptions	45	55	83
P3	Globally coordinated climate policies with delayed (i.e., from 2030 onwards or after 2030) action, preceded by	341	451	502
P3a	– no mitigation commitment or current national policies	3	7	9
P3b	– NDCs	322	426	464
P3c	– NDCs and additional policies	16	18	29
P4	Cost-benefit analysis	2	2	2
	Total	1202	1686	2266

A.III.II.3.3 National and Regional Pathways

National and regional pathways have been collected in the AR6 scenario database to support the Chapter 4 assessment. In total more than 500 pathways for 24 countries/regions have been submitted to the AR6 scenario database by integrated assessment, energy-economic and computable general equilibrium modelling research teams. This represents a limited sample of the overall literature on mitigation pathways at the national level. The majority of these pathways originate

from a set of larger model intercomparison projects, JMIP/EMF35 (Sugiyama et al. 2020a) focusing on Japan, CD-LINKS (Roelfsema et al. 2020; Schaeffer et al. 2020), COMMIT (van Soest et al. 2021), ENGAGE (Fujimori et al. 2021), and Paris Reinforce (Perdana et al. 2020; Nikas et al. 2021) each covering several countries/regions from the following: Australia, Brazil, China, EU, India, Indonesia, Japan, Korea, Russia, Thailand, USA, Vietnam. The remaining pathways stem from individual modelling studies that submitted scenarios to the database (Table 18).

A.III.II.3.4 Sector Transition Pathways

Sectoral transition pathways based on the AR6 scenario database are addressed in a number of Chapters, primarily Chapter 6 (Energy systems), Chapter 7 (AFOLU), Chapter 9 (Buildings), Chapter 10 (Transport) and Chapter 11 (Industry). These analyses cover both contributions from global IAMs and from sector-specific models with regional or global coverage. The assessments cover a variety

of perspectives, including long-term global and macro-region trends for the sectors, sectoral analysis of the Illustrative Pathways, and comparison of the scenarios between full-economy IAMs and sector-specific models on shorter time horizons. These perspectives have a bi-directional utility – to understand how well IAMs are representing sectoral trends from more granular models, and to position sectoral models in the context of full-economy transitions to verify consistency with different climate outcomes.

Table 19 | Overview of how models and scenarios were used in sectoral chapters. All scenario and model counts listed in the table are contained in the AR6 scenario database, with the exception of Chapter 9 (Buildings), which supplemented its dataset with a large number of scenarios separately pulled from the sectoral literature. Scenario counts represents unique model-scenario combinations in the database.

Sector	Number of models	Number of scenarios	Key sections	Key perspectives
Energy systems (Chapter 6)	12 18 13	476 536 776	6.6 6.7 6.7.1	Regional and global energy system characteristics along mitigation pathways and at net-zero emissions specifically: CO ₂ and GHG emissions; energy resource shares; electricity and hydrogen shares of final energy; energy intensity; per-capita energy use; peak emissions; energy investments
AFOLU (Chapter 7)	11 14 13 3	384 572 559 4	7.5.1 7.5.2 7.5.4 7.5.5	Regional and global GHG emissions and land use dynamics; economic mitigation potential for different GHGs; integrated mitigation pathways
Buildings (Chapter 9)	80 (of which 2 are in AR6 scenario database)	82 (of which 4 are in AR6 scenario database)	9.3, 9.6	A mixture of top-down and bottom-up models. The former were either national, regional or global while the latter were global only with a breakdown per end use, building type, technologies and energy carrier
Transport (Chapter 10)	24	1210	10.7	Global and regional transport demand, activity, modes, vehicles, fuels, and mitigation options
Industry (Chapter 11)	14	508	11.4.2	Global final energy use, CO ₂ emissions, carbon sequestration, fuel shares

Note 1: The number of models and scenarios reported in the table cannot be summed across chapters, as there is considerable overlap in selected model-scenario combinations across chapters, depending on the filtering processes used for relevant analyses. Moreover, the numbers in the table – and certainly not their sum – are not intended to match those reported for the global pathways assessed by Chapter 3 in Section II.3.2.

Note 2: Numbers shown in the model-count column are arrived at through the authors' best judgement. This has to do with the overlapping nature of unique model versions (within a given model family) as models evolve over time. In this case, model versions with substantial overlap were considered the same model, whereas model versions that differ significantly were counted as unique. For example, MESSAGEix-GLOBIOM 1.0 and MESSAGEix-GLOBIOM_1.1 are counted as the same model, while MESSAGEix-GLOBIOM 1.0 and MESSAGE are counted as different. If instead counting all model versions uniquely, then the following counts would apply to each chapter: Energy systems (30/38/29), AFOLU (18/27/25/4), Buildings (80), Transport (50), Industry (32).

Note 3: The Transport chapter figures in Chapter 10, Section 10.7, are produced from the final AR6 scenario database by the code accompanying this report. The set of model and scenario names appearing in each plot or figure of Section 10.7 varies, depending on whether particular submissions to the database included the specific variables appearing in that plot. Authors advise inspecting the data files accompanying each figure for the set of models/scenarios specific to that figure, or running the code against the final database snapshot to reproduce the figures in question.

University of Helsinki
Finland

TYLECOTE, Andrew

University of Sheffield
United Kingdom (of Great Britain
and Northern Ireland)

UEDA, Tatsuki

National Agriculture and Food Research
Organization
Japan

UGOM, Michael

University of Nigeria, Nsukka
Nigeria

UMEMIYA, Chisa

Institute for Global Environmental Strategies
Japan

URBAN, Frauke

KTH Royal Institute of Technology
Sweden

UTTURKAR, Mayuri

University of Delaware
The United States of America

UVAROVA, Galyna

Green Climate Fund, Independent
Evaluation Unit
The Republic of Korea

UZZAMAN, Md Arfan

Food and Agriculture Organization
of the United Nations (FAO)
Bangladesh

VAKKILAINEN, Esa

LUT University, Lappeenranta
Finland

VALDOVINOS, Claudio

University of Concepcion
Chile

VAN ASSELT, Harro

University of Eastern Finland
The Netherlands

VAN BERKEL, Dennis

Urgenda
The Netherlands

VAN DE GRAAF, Thijs

Ghent University
Belgium

VAN DEN BROEK, Machteld

Utrecht University
The Netherlands

VAN DER VOORN, Tom

Institute for Environmental Systems
Research
The Netherlands

VAN DIEMEN, Renee

WG III TSU
United Kingdom (of Great Britain
and Northern Ireland)

VAN DRUTEN, Emiel

Technical University of Eindhoven
The Netherlands

VAN GOETHEM, Georges

Royal Academy of Overseas
Sciences of Belgium (ARSOM – KAOW)
Belgium

VAN HERPEN, Maarten

Acacia Impact Innovation BV
The Netherlands

VAN SLUISVELD, Mariesse

PBL Netherlands Environmental
Assessment Agency
The Netherlands

VAN 'T WOUT, Tamara

Food and Agriculture Organization
of the United Nations (FAO)
Qatar

VAN WIJK, Ad

Technical University Delft
The Netherlands

VAN YPERSELE, Jean-Pascal

Université catholique de Louvain
Belgium

VANDERSTRAETEN, Martine

Belgian Science Policy Office (BELSPO)
Belgium

VANDYCK, Toon

Institute of Mountain Hazards
and Environment, Chinese Academy
of Sciences
China

ZHOU, Nan

U.S. Department of Energy
The United States of America

ZHOU, Yuyu

Iowa State University
The United States of America

ZHUANG, Guotai

China Meteorological Administration
China

ZIMM, Caroline

International Institute for Applied Systems
Analysis (IIASA)
Austria

ZOBAA, Ahmed

Brunel University London
United Kingdom (of Great Britain
and Northern Ireland)

ZOMMERS, Zinta

United Nations Office for Disaster
Risk Reduction
Germany

ZUHAIB, Sheikh

Buildings Performance Institute
Europe asbl (BPIE)
Germany

Annex VI: Acronyms

This chapter should be cited as:

IPCC, 2022: Annex VI: Acronyms. In *Climate Change 2022: Mitigation of Climate Change. Contribution of Working Group III to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* [P.R. Shukla, J. Skea, R. Slade, A. Al Khourdajie, R. van Diemen, D. McCollum, M. Pathak, S. Some, P. Vyas, R. Fradera, M. Belkacemi, A. Hasija, G. Lisboa, S. Luz, J. Malley, (eds.)]. Cambridge University Press, Cambridge, UK and New York, NY, USA. doi: 10.1017/9781009157926.025.

A/R	afforestation/reforestation	BASIC	Brazil, South Africa, India and China
AB	Assembly Bill	BAT	best available technology
AC	alternating current	BAU	business as usual
ACCTS	Agreement on Climate Change, Trade and Sustainability	BC	black carbon
ACF	areal carbon footprint	BCA	border carbon adjustment
ADEME	Agence de l'Environnement et de la Maîtrise de l'Energie (French Environment and Energy Management Agency)	BECCS	bioenergy with carbon capture and storage
AF	Adaptation Fund	BEES	building energy efficiency standards
AFR	Africa	BEMS	building energy management systems
AFD	French Development Agency	BEV	battery electric vehicle
AFOLU	agriculture, forestry and other land use	BF-BOF	blast furnace-basic oxygen furnace
AGAGE	Advanced Global Atmospheric Gases Experiment	BIM	Building Information Modelling
AI	artificial intelligence	BIPV	building-integrated photovoltaic
AILAC	Association of the Latin American and Caribbean Countries	BLUE	Bookkeeping of land-use emissions
ALBA	Alianza Bolivariana para los Pueblos de Nuestra América (Bolivarian Alliance for the Peoples of our Americas)	BR	biennial report
ALCA	Attributional Life Cycle Assessment	BRI	Belt and Road Initiative
AM	additive manufacturing	BRT	bus rapid transport
APEC	Asia-Pacific Economic Cooperation	BTR	biennial transparency report
AR4	Fourth Assessment Report of the Intergovernmental Panel on Climate Change	BTU	British thermal units
AR5	Fifth Assessment Report of the Intergovernmental Panel on Climate Change	BUR	biennial update report
AR6	Sixth Assessment Report of the Intergovernmental Panel on Climate Change	CA	capability approach
AR7	Seventh Assessment Cycle of the Intergovernmental Panel on Climate Change	CAT	Climate Action Tracker
ARC	African Risk Capacity	CAGR	compound annual growth rate
ARPA-E	Advanced Research Projects Agency-Energy	CAIT	Climate Analysis Indicators Tool
ART	Architecture for REDD+ Transactions	CAPEX	capital expenditure
Art.	Article (e.g., of the UNFCCC)	CAR	Climate Action Reserve
ASAP	Adaptation for Smallholder Agriculture Programme	CBA	cost-benefit analysis
ASCM	Agreement on Subsidies and Countervailing Measures	CBAM	carbon border adjustment mechanism
ASI	Avoid-Shift-Improve	CBCF	consumption-based carbon footprint (accounting)
ASK	available seat kilometres	CBD	Convention on Biological Diversity
AUM	assets under management	CBDRRRC	common but differentiated responsibilities and respective capabilities
		CBEs	consumption-based emissions
		CCAC	Climate and Clean Air Coalition
		CCD	climate-compatible development
		CCPI	Climate Change Performance Index
		CCRIF	Caribbean Catastrophe Risk Insurance Facility
		CCS	carbon capture and storage
		CCT	cirrus cloud thinning

CCU	carbon capture and utilisation	COP	Conference of the Parties to the UNFCCC
CCUS	carbon capture, use and storage	CORSIA	Carbon Offsetting and Reduction Scheme for International Aviation
CCX	Chicago Climate Exchange	CPRS	Climate Policy Relevant Sectors
CD	charge depleting	CPTPP	Comprehensive and Progressive Agreement for Trans-Pacific Partnership
CDD	cooling degree-days	CRD	climate-resilient development
CDIAC	Carbon Dioxide Information Analysis Center	CREMAs	Community Resource Management Area Mechanisms (Ghana)
CDM	Clean Development Mechanism	CRF	common reporting format
CDR	carbon dioxide removal	CRIBs	Climate Relevant Innovation-system Builders
CE	circular economy	CS	charge sustaining
CEA	cost-effectiveness analysis	CSC	climate-smart cocoa
CEDS	Community Emissions Data System	CSI	Cement Sustainability Initiative
CETA	EU-Canada Comprehensive Economic and Trade Agreement	CSP	concentrating solar power
CFCs	chlorofluorocarbons	CSR	corporate social responsibility
CfD	contract for difference	CSSP	cross-sector social partnership
CFL	compact fluorescent lamp [lighting]	CTCN	Climate Technology Centre and Network
CGE	Computable General Equilibrium	CurPol	Current Policies scenario
CGTP	combined global temperature change potential	DAC	direct air capture
CH₄	methane	DACCS	direct air carbon capture and storage
CHP	combined heat and power	DACCU	direct air capture carbon and utilisation
CII	Carbon Intensity Indicator	DALY	disability adjusted life year
CLASP	Collaborative Labelling and Appliance Standards Program	DBH	diameter at breast height
CLC	constant land cover	DC	direct current
CLCA	Consequential Life Cycle Assessment	DGVM	dynamic global vegetation model
CLIMI	Climate Laws, Institutions and Measures Index	DLS	decent living standards
CLRTAP	Convention on Long-Range Transboundary Air Pollution	DRI	direct reduced iron
CLT	cross-laminated timber	DSM	demand-side management
CMA	Conference of the Parties serving as the meeting of the Parties to the Paris Agreement	DWM	down woody material
CMIP6	Coupled Model Intercomparison Project Phase 6	EaaS	energy as a service
CNG	compressed natural gas	EAF	electric arc furnace
CO	carbon monoxide	EBEs	extraction-based emissions
CO₂	carbon dioxide	EDGAR	Emissions Database for Global Atmospheric Research
CO₂-eq	carbon dioxide equivalent	EDLC	electrochemical double layer capacitor
COMMIT	Climate policy assessment and Mitigation Modelling to Integrate national and global Transition pathways	EEA	Eastern Europe and West Central Asia
CoP	coefficient of performance	EED	Energy Efficiency Directive
		EEDI	Energy Efficiency Design Index
		EEE	emissions embodied in exports
		EEl	emissions embodied in imports

EEM	Energy Efficient Mortgage	FBDG	food-based dietary guidelines
EES	electrical energy storage	FCDO	UK Foreign, Commonwealth and Development Office
EET	emissions embodied in trade	FCV	fuel cell vehicle
EEXI	Energy Efficiency Existing Ship Index	FDI	Foreign Direct Investment
EF	emission factor	FFI	fossil fuel and industry
EGR	exhaust gas recirculation	F-gas	fluorinated gas
EGTT	Expert Group on Technology Transfer	FIC	Faster Innovation Case
EIMs	Energy Improvement Mortgages	FiT	feed-in tariff
EIP	energy and industrial processes	FiTP	feed-in premium
EJ	exajoule	FLEGT	Forest Law Enforcement, Governance and Trade
E_{LUC}	land-use change emissions	FLW	food loss and waste
EMAS	Eco-Management and Auditing Scheme	FRAND	fair, reasonable and non-discriminatory
EPD	Environmental Product Declaration	FSC	Forest Sustainability Council
EPBD	Energy Performance Buildings Directive	FT	Fischer-Tropsch
EPCs	Energy Performance Certificates	FTA	free trade agreement
EPS	Emissions Performance Standard	FWM	fine woody material
EPR	extended producer responsibility	GATS	General Agreement on Trade in Services
ERF	effective radiative forcing	GATT	General Agreement on Tariffs and Trade
ERIA	Economic Research Institute for ASEAN and East Asia	GBAM	ground-based albedo modifications
ES-FiT	Energy Savings Feed-in Tariff	GCAM	Global Change Assessment Model
ESCO	Energy Service Company	GCCA	Global Cement and Concrete Association
ESA	energy services agreement	GCF	Green Climate Fund
ESD	education for sustainable development	GCoM	Global Covenant of Mayors
ESG	environmental, social and governance	GCP	Global Carbon Project
ESM	energy systems model	GDP	gross domestic product
ETP	<i>Energy Technology Perspectives</i> (IEA report)	GEA	Global Energy Assessment
ETS	Emissions Trading System	GEF	Global Environment Facility
EU	European Union	GFBI	Global Forest Biodiversity Initiative
EU-27	European Union member states [excluding UK]	GFCA	Global Framework for Climate Action
EU-28	European Union member states [including UK]	GFCF	Gross-fixed capital formation
EU ETS	European Union Emissions Trading Scheme	GFED	Global Fire Emissions Database
EU-RED	EU Renewable Energy Directive	GHG	greenhouse gas
EV	electric vehicle	GIS	geographic information system
EW	enhanced weathering	GIS	global innovation system
FaIR	Finite Amplitude Impulse Response	GIZ	the German Development Agency (<i>Deutsche Gesellschaft für Internationale Zusammenarbeit</i>)
FAQ	frequently asked question	GJ	gigajoule
FAO	Food and Agriculture Organization of the United Nations	GMF	Global Methane Fund

GMI	Global Methane Initiative	ICJ	International Court of Justice
GMRIO	global multi-region input-output	ICT	information and communication technology
GNI	gross national income	IDDRI	Institute for Sustainable Development and International Relations
GPP	Green Public Procurement	IEA	International Energy Agency
GPT	general-purpose technologies	IFC	International Finance Corporation
GSAT	Global Surface Air Temperature	IFDD	Institut de la Francophonie pour le Développement Durable (Francophonie Institute for Sustainable Development)
Gt	gigatonne	IFI	international financial institution
GtCO₂-eq	gigatonnes of CO ₂ equivalent	IGCC	International Green Construction Code
GTEM	global transport energy sectoral models	IIASA	International Institute for Applied Systems Analysis
GTP	global temperature change potential	IIGCC	Institutional Investors Group on Climate Change
GWP	global warming potential	IIASA	International Institute for Applied Systems Analysis
GWP100	100-year global warming potential	IloT	industrial internet of things
HAP	household air pollution	ILB	incandescent light bulb
HCE	historical cumulative emission	ILM	intrusive load monitoring
HCFCs	hydrochlorofluorocarbons	IMF	International Monetary Fund
HCS	High Carbon Stock	IMO	International Maritime Organization
HDI	Human Development Index	IMP	Illustrative Mitigation Pathway
H-DRI	Hydrogen-based direct reduced iron	IMP-GS	Illustrative Mitigation Pathway – Gradual Strengthening
HDV	Heavy-duty vehicles	IMP-LD	Illustrative Mitigation Pathway – Low Demand
HEMS	home energy management system	IMP-Neg	Illustrative Mitigation Pathway – Net Negative Emissions
HES	Hybrid energy storage	IMP-Ren	Illustrative Mitigation Pathway – Renewable Electricity
HEV	hybrid electric vehicle	IMP-SP	Illustrative Mitigation Pathway – Shifting Pathways
HFC	hydrofluorocarbon	INDC	Intended Nationally Determined Contributions
HFCV	hydrogen fuel cell vehicle	IoT	internet of things
HIHD	Historical Index of Human Development	IPBES	Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services
HLPF	High-Level Political Forum	IPCC	Intergovernmental Panel on Climate Change
HN	Houghton and Nassikas	IP	Illustrative Pathway
HSR	high-speed rail	IPP	independent power producers
HVAC	heating, ventilation and air conditioning	IPPU	Industrial processes and product use
HVO	hydrotreated vegetable oil	IPR	intellectual property rights
HYDE	History database of the Global Environment	IRENA	International Renewable Energy Agency
IAGA	International Air Transport Association	IRP	UN International Resource Panel
IAM	integrated assessment model		
IBE	income-based emission accounting		
ICAO	International Civil Aviation Organization		
ICCT	International Council on Clean Transportation		
ICE	internal combustion engine		
ICEV	internal combustion engine vehicles		
ICI	international cooperative initiative		

ISDS	investor–state dispute settlement	MAPS	Mitigation Action Plans and Scenarios
ITF	International Transport Forum	mbpd	million barrels per day
ITMO	internationally transferred mitigation outcome	MCB	marine cloud brightening
ITUC	International Trade Union Confederation	MDB	multilateral development bank
JICA	Japanese International Cooperation Agency	ME	material efficiency
JRC	GECO Joint Research Centre – Global Energy and Climate Outlook	MES	material efficiency scenario
KR	key risks	MEA	multilateral environmental agreement
kWh	kilowatt hour	MEPC	Marine Environment Protection Committee
LAM	Latin America and the Caribbean	MEPSs	Minimum Energy Performance Standards
LCA	life cycle assessment <i>or</i> life cycle analysis	Mha	million hectares
LCC	lifecycle costs	MIGA	Multilateral Investment Guarantee Agency
LCCE	levelised cost of conserved energy	MIS	mission-oriented innovation systems
LCCC	levelised cost of conserved carbon	MJ	megajoule
LCOE	levelised cost of electricity <i>or</i> levelised cost of energy	Mkm²	million square kilometres
LCS	low-carbon society	MLP	multi-level perspective
LDCs	Least-Developed Countries	ModAct	Moderate Action scenario
LDCF	Least Developed Countries Fund	MOE	molten oxide electrolysis
LDN	Land Degradation Neutrality	MOOC	massive open online course
LDV	light-duty vehicle	MPa	megapascal
LEAF	Lowering Emissions by Accelerating Forest Finance	MRV	measuring, reporting and verifying <i>or</i> measuring, reporting and verification
LED	light-emitting diode	MS	member state
LED scenario	Low Energy Demand scenario	MSME	micro, small and medium enterprises
LEDs	low-emissions development strategies	Mt	megatonne
LIB	lithium-ion battery	MTA	methanol-to-aromatics
LiRE	IMAGE-Lifestyle-Renewable (IEA scenario)	MTO	methanol-to-olefins
LNG	liquefied natural gas	MWh	megawatt hour
LPG	liquefied petroleum gas	N₂O	nitrous oxide
LTGG	long-term global goal (to hold the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels)	NAFTA	North American Free Trade Agreement
LTO	long-term operation	NAMA	Nationally Appropriate Mitigation Actions
LULUCF	land use, land-use change and forestry	NAP	national adaptation plan
LUM	land-use model	NAZCA	Non-State Actor Zone for Climate Action
MA	Mitigation Alliance	NBS	nature-based solutions
MaaS	Mobility as a Service	NDC	Nationally Determined Contribution
MAC	marginal abatement cost	NEDO	New Energy and Industrial Technology Development Organisation, Japan
MACC	marginal abatement cost curve	NELD	non-economic loss and damage
		NF₃	nitrogen trifluoride
		NGFS	Network for Greening the Financial System
		NGHGI	national greenhouse gas inventories

Acronyms

NGO	non-governmental organisation	PCRAFI	Pacific Catastrophe Risk Assessment and Financing Initiative
NiCD	nickel–cadmium	PDB	public development bank
NILM	non-intrusive load monitoring	PEFC	Programme for the Endorsement of Forest Certification
Nimby	Not in my back yard	PEMFC	proton-exchange membrane fuel cells
NiMH	nickel-metal hydride	PES	payment for ecosystem services
NIS	national innovation system	PFCs	perfluorocarbons
NMVOC	non-methane volatile organic compounds	PHEV	plug-in hybrid electric vehicle
NOAA	National Oceanic and Atmospheric Administration	pkm	passenger-kilometres
NRG	natural regrowth	PM	particulate matter
NR	Non-Residential	PPA	Power Purchase Agreement
NSA	non-state actor	PPCA	Powering Past Coal Alliance
NTEM	national transport -energy models	PPCR	Pilot Program for Climate Resilience
NT	Non-technological	PPI	pulp and paper industry
NZE	net zero emissions	PPP	public-private partnership
NZE scenario	Net-Zero Emissions by 2050 (IEA scenario)	PPP	purchasing power parity
NZEB	net zero energy building	PRI	Principles for Responsible Investment
nZEB	nearly zero energy building	PV	photovoltaic
NSTT	North–South technology transfer and cooperation	QE	quantitative easing
NUA	New Urban Agenda	R&D	research and development
NYDF	New York Declaration on Forests	RCEP	Regional Comprehensive Economic Partnership
OA	ocean alkalinity	RCM	reduced complexity model
OAC	ocean albedo change	RCP	Representative Concentration Pathway
OAE	ocean alkalinity enhancement	RD&D	research, development and demonstration
ODA	overseas development assistance	RDI	Research, Development and Innovation
ODS	ozone-depleting substance	RECC	Resource Efficiency and Climate Change
OECD	Organisation for Economic Co-operation and Development	RECC-LED	Resource Efficiency and Climate Change-Low Energy Demand (IEA scenario)
OF	ocean fertilisation	REDD+	reducing emissions from deforestation and forest degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks
OPEC	Organization of the Petroleum Exporting Countries	REEs	rare earth elements
OPEX	operating and maintenance expenditures	ReSOLVE	Regenerate, Share, Optimise, Loop, Virtualise, Exchange framework
OS	overshoot	RGGI	Regional Greenhouse Gas Initiative
OSS	one-stop shop	RIMAP	Real-time Integrated Model for probabilistic Assessment of emissions Paths
P2P	peer-to-peer	RIS	regional innovation systems
PA	The Paris Agreement	RKR	Representative Key Risks
PACE	Property Assessed Clean Energy		
PBEs	production-based emissions		
PCCB	Paris Committee on Capacity-building		
PCF	personal carbon footprint		

RPK	revenue passenger-kilometres	SLoCaT	Sustainable Low Carbon Transport Partnership
RSD	relative standard deviation	SLM	sustainable land management
RSPO	Roundtable on Sustainable Palm Oil	SLR	sea level rise
RTS	Reference Technology Scenario	SM	smart manufacturing
S&L	standards and labelling	SMEs	small and medium-sized enterprises
SAF	sustainable aviation fuel	SNA	System of National Accounts
SAI	stratospheric aerosol interventions	SNTT	South–North technology transfer and cooperation
SAM	Social Accounting Matrix	SO₂	sulphur dioxide
SAR	Second Assessment Report	SOE	state-owned enterprise
SARPs	Standards and Recommended Practices	SOFC	solid oxide fuel cell
SASB	Sustainability Accounting Standards Board	SPM	Summary for Policymakers
SBSTA	Subsidiary Body for Scientific and Technological Advice	SPV	special purpose vehicle
SBT	science-based target	SR1.5	IPCC Special Report on Global Warming of 1.5°C
SCC	social cost of carbon	SRCCCL	IPCC Special Report on Climate Change and Land
SCCF	Special Climate Change Fund	SRI	Sustainable and Responsible Investment
SCS	soil carbon sequestration	SRM	solar radiation modification
SDG	Sustainable Development Goal	SROCC	IPCC Special Report on the Ocean and Cryosphere in a Changing Climate
SDPS	shifting development pathways to increased sustainability	SSC	South-South cooperation
SDR	Special Drawing Rights	SSP	Shared Socio-economic Pathway
SDS	Sustainable Development Scenario (IEA scenario)	SSTT	South–South technology transfer and cooperation
SDSN	Sustainable Development Solutions Network	STEM	science, technology, engineering and mathematics
SE	sustainable entrepreneur	STEPS	Stated Policies Scenario
SEA	strategic environmental assessment	SUV	sport utility vehicle
SEADRIF	South East Asian Disaster Risk Insurance Facility	TA	territorial accounting
SEC	specific energy consumption	TABS	thermally activated building systems
SECA	sulphur emission control area	TBT Agreement	WTO Agreement on Technical Barriers to Trade
SEEMP	Ship Energy Efficiency Management Plan	TCBA	technology-adjusted consumption-based emission accounting
SEM	structural equations modelling	TCFD	Task Force on Climate-related Financial Disclosures
SER	Sufficiency, Efficiency, Renewal	TCRE	transient climate response to cumulative emissions of carbon dioxide
SETAC	Society of Environmental Toxicology and Chemistry (UNEP-SETAC)	TDR	travel demand reduction
SF₆	sulphur hexafluoride	TEEB	The Economics of Ecosystems and Biodiversity
SI	sustainable intensification	TEC	Technology Executive Committee
SIDS	Small Island Developing States	TES	Transforming Energy Scenario
SIS	sectoral innovation system		
SLCF	short-lived climate forcer		
SLCP	short-lived climate pollutant		

Acronyms

TIS	technological innovation system	VNR	Voluntary National Review
TFC	total final energy consumption	WBCSD	World Business Council on Sustainable Development
TGC	tradeable green certificate	WEFN	water-energy-food nexus

Index

This chapter should be cited as:

IPCC, 2022: Index. In IPCC, 2022: *Climate Change 2022: Mitigation of Climate Change. Contribution of Working Group III to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* [P.R. Shukla, J. Skea, R. Slade, A. Al Khourdajie, R. van Diemen, D. McCollum, M. Pathak, S. Some, P. Vyas, R. Fradera, M. Belkacemi, A. Hasija, G. Lisboa, S. Luz, J. Malley, (eds.)]. Cambridge University Press, Cambridge, UK and New York, NY, USA. doi: 10.1017/9781009157926.026

*Note: * indicates the term also appears in the Glossary and n indicates a footnote. Italicised page numbers denote tables, figures, associated captions and boxed material. Bold page numbers indicate entire chapter spans..*

1.5°C pathway* 14–25, 15–16, 21–23, 26–27, 44, 174–175, 175, 274, 298–299, 332, 424–426, 435, 1585, 1585, 1871
carbon lock-in and stranded assets 28, 188, 697, 698
co-benefits and trade-offs 376, 1741–1742
emissions gap 14, 14
energy system scenarios 436–437, 615, 625–626, 685–700, 685–692, 694–695, 698, 699, 703
fossil fuels use and phase-out 267, 438, 625–626, 698–700
high renewable accelerated pathways 436–437
industry sector 1199–1200, 1200
investment and finance 158–159, 300, 1550
land occupation and mitigation 1297, 1298
mitigation costs 156, 703
and net zero 174, 324, 325–327, 328, 329, 337
remaining carbon budget 6–7, 174, 188, 319, 349
sectoral strategies 337
technology cost and deployment 1658, 1658–1659
see also long-term goal compatible mitigation pathways

1.5°C scenarios 433–435, 1742, 1743, 1873

2°C pathways 14–25, 14, 15–16, 21–23, 26–27, 174–175, 175, 274, 298–300, 332, 351, 424–426, 435, 1585, 1585
carbon budgets 174, 1874
co-benefits and trade-offs 377, 1741–1742
energy system scenarios 436, 615, 625–626, 685–700, 685–692, 694–695, 698, 699, 703
fossil fuel use and phase-out 267, 438, 625–626, 698–700
industry sector 1199–1200, 1200
land occupation and mitigation 1297, 1298
mitigation costs 156, 703
and net zero 174, 324, 325–327, 328, 329, 337
sectoral strategies 337
technology cost and deployment 1658, 1658–1659
see also long-term goal compatible mitigation pathways

2°C Scenario (2DS) 1201, 1202, 1203

2°C scenarios 32, 193, 431, 433, 698–700, 1201, 1202, 1203, 1742, 1743, 1873

2030 Agenda for Sustainable Development 155, 1455–1456, 1485, 1486, 1498, 1732–1733, 1738–1739

A

absolute decoupling 242, 243, 243, 244, 274, 452, 513

absorptive capacity 1676, 1685

accelerating mitigation 40, 45, 153–154, 411–413, 414, 415–447, 477, 1409–1411, 1412, 1694
behaviour and lifestyle changes 412, 440, 460, 463–464, 505
cross-sector and economy-wide system change 1359, 1406–1411
demand-side measures 512
enabling conditions 412–413, 414, 459–464, 460, 1359, 1407
equity and just transitions 189, 472–474, 474, 475, 517–518, 1407
impact on development objectives 411, 442–446
international cooperation 356–358, 471, 1410
obstacles 411, 446–447, 446, 447
pathways 356–358, 357, 435–442, 436–437, 476
policies 412–413, 444, 460, 461
policy integration 461, 464–468, 471, 1359, 1394
public support 1358
risks and uncertainties 471–472
and shifting development pathways 414–415, 459–468, 471–472
societal perspective 517–518, 1358
unsuitable ‘structures’ 446, 447

accelerating transition 45, 185, 255, 256–259, 562–564, 565, 1772

accelerating transition in sustainable development context 147, 1727–1772
adaptation and mitigation 1756–1759, 1771
AFOLU sector 1749–1751, 1770–1771
barriers 1729, 1730–1731, 1764–1770, 1771
cities, infrastructure and transport 1755–1756, 1770
cross-sectoral transitions 1749–1764, 1770
digitalisation 1730, 1759–1761
enabling conditions 1729, 1730–1731, 1764–1770, 1771
factors influencing transitions 1729, 1734–1738, 1770
FAQs 1772
governance 1729, 1735–1736, 1767–1768, 1772
industry 1754–1755
institutional factors 1735–1736, 1767–1768, 1772
international cooperation 1732–1734, 1735, 1736
just transition 1729, 1730, 1731, 1745–1749, 1768–1769
pathways and scenarios 1739–1742
policy coherence and integration 1731, 1733, 1736, 1758, 1759, 1769
political economy 1735–1736, 1743, 1748, 1768, 1770
renewable energy penetration and fossil fuel phase-out 1742–1749, 1743, 1771
short-term and long-term transitions 1738–1739
stranded assets 1730, 1744–1745, 1747, 1771
synergies and trade-offs 1729–1730, 1749–1751, 1753–1754, 1755, 1756, 1757–1758, 1759–1760, 1761–1764, 1762, 1770–1771
systems-level perspective 1737–1738, 1770
transition process 1748–1749
water-energy-food nexus 1751–1754, 1758, 1759, 1760–1761

acceptability of policy or system change* 382, 556, 702–703, 1658
carbon taxes 466, 507
CDR methods 1277, 1279
fossil fuels 648
nuclear power 640–641
renewable energy 633, 637, 639, 646, 649

access
to finance 1321, 1549, 1550
to food 1279–1280
to modern energy services* 9, 622–623, 623–624, 1000–1001, 1001
for clean cooking 517, 548, 559, 623, 623, 1003–1004, 1603–1604
electrification co-benefits 705, 1001, 1003–1004
and emissions 218, 254–255
energy security 1005
inequity 516–521
to services 514, 515, 516–517, 517–518
to technology and infrastructure services 517–518
see also energy access*

action research 1737

active travel/transport 908, 909, 926, 1052

activism 165, 506, 525, 556–557, 1374–1375, 1375, 1508–1509, 1765
see also climate litigation

adaptation* 40–43, 525–527, 1207
adaptive management 1406
buildings 956, 996–998
capacity building 1686
finance/financing needs 915–916, 1550, 1554, 1555, 1573–1574
international cooperation 1404–1405, 1474, 1686
and just transitions 1747
and mitigation 1359, 1400–1405, 1402, 1403–1404
AFOLU sector 753–754, 830
and bioeconomy 1307–1311
development pathways 468–471
sustainable development context 1401–1403, 1756–1759, 1771
National Adaptation Plans (NAPs) 1401, 1574
Paris Agreement 1474
synergies and trade-offs 1400–1403, 1401, 1729, 1756–1759
technology and innovation 1686, 1699
transport sector 1057

frequently asked questions (FAQs)
 1.1: What is climate change mitigation? 194
 1.2: Which greenhouse gases (GHGs) are relevant to which sectors? 194

1.3: What is the difference between 'net zero emissions' and 'carbon neutrality'? 194
 2.1: Are emissions still increasing or are they falling? 274
 2.2: Are there countries that have reduced emissions and grown economically at the same time? 274
 2.3: How much time do we have to act to keep global warming below 1.5 degrees? 274
 3.1: Is it possible to stabilise warming without net negative CO₂ and GHG emissions? 385
 3.2: How can net zero emissions be achieved and what are the implications of net zero emissions for the climate? 385
 3.3: How plausible are high emissions scenarios, and how do they inform policy? 386
 4.1: What is to be done over and above countries' existing pledges under the Paris Agreement to keep global warming well below 2°C? 477
 4.2: What is to be done in the near term to accelerate mitigation and shift development pathways? 477
 4.3: Is it possible to accelerate mitigation in the near term while there are so many other development priorities? 477
 5.1: What can every person do to limit warming to 1.5°C? 572
 5.2: How does society perceive transformative change? 572
 5.3: Is demand reduction compatible with growth of human well-being? 572
 6.1: Will energy systems that emit little or no CO₂ be different than those of today? 707
 6.2: Can renewable sources provide all the energy needed for energy systems that emit little or no CO₂? 707
 6.3: What are the most important steps to decarbonise the energy system? 707
 7.1: Why is the Agriculture, Forestry and Other Land Uses (AFOLU) sector unique when considering GHG mitigation? 831
 7.2: What AFOLU measures have the greatest economic mitigation potential? 831
 7.3: What are potential impacts of large-scale establishment of dedicated bioenergy plantations and crops and why is it so controversial? 831
 8.1: Why are urban areas important to global climate change mitigation? 927
 8.2: What are the most impactful options cities can take to mitigate urban emissions, and how can these be best implemented? 927
 8.3: How do we estimate global emissions from cities, and how reliable are the estimates? 927
 9.1: To which GHG emissions do buildings contribute? 1018
 9.2: What are the co-benefits and trade-offs of mitigation actions in buildings? 1018
 9.3: Which are the most effective policies and measures to decarbonise the building sector? 1018

10.1: How important is electromobility in decarbonising transport and are there major constraints in battery minerals? 1120
 10.2: How hard is it to decarbonise heavy vehicles in transport like long-haul trucks, ships and planes? 1120
 10.3: How can governments, communities and individuals reduce demand and be more efficient in consuming transport energy? 1121
 11.1: What are the key options to reduce industrial emissions? 1224
 11.2: How costly is industrial decarbonisation and will there be synergies or conflicts with sustainable development? 1224
 11.3: What needs to happen for a low-carbon industry transition? 1224
 12.1: How could new technologies to remove carbon dioxide from the atmosphere contribute to climate change mitigation? 1322
 12.2: Why is it important to assess mitigation measures from a systemic perspective, rather than only looking at their potential to reduce GHG emissions? 1322
 12.3: Why do we need a food systems approach for assessing GHG emissions and mitigation opportunities from food systems? 1322
 13.1: What roles do national play in climate mitigation, and how can they be effective? 1413
 13.2: What policies and strategies can be applied to combat climate change? 1413
 13.3: How can actions at the sub-national level contribute to climate mitigation? 1413
 14.1: Is international cooperation working? 1517
 14.2: What is the future role of international cooperation in the context of the Paris Agreement? 1517
 14.3: Are there any important gaps in international cooperation, which will need to be filled in order for countries to achieve the objectives of the Paris Agreement, such as holding temperature increase to well below 2°C and pursuing efforts towards 1.5°C above pre-industrial levels? 1517
 15.1: What's the role of climate finance and the finance sector for a transformation towards a sustainable future? 1610
 15.2: What's the current status of global climate finance and the alignment of global financial flows with the Paris Agreement? 1610
 15.3: What defines a financing gap, and where are the critically identified gaps? 1610
 16.1: Will innovation and technological changes be enough to meet the Paris Agreement objectives? 1701
 16.2: What can be done to promote innovation for climate change and the widespread diffusion of low-emission and climate-resilient technology? 1701

- 16.3: What is the role of international technology cooperation in addressing climate change? 1701
- 17.1: Will decarbonisation efforts slow or accelerate sustainable development transitions? 1772
- 17.2: What role do considerations of justice and inclusivity play in the transition towards sustainable development? 1772
- 17.3: How critical are the roles of institutions in accelerating the transition and what can governance enable? 1772
